HEPATOBILIARY MANIFESTATIONS IN INFLAMMATORY BOWEL DISEASE: RAISING CONCERN ON AN OLD DILEMMA (Abstract): Inflammatory bowel disease (IBD) is increasingly recognized as a multisystem disorder with significant extraintestinal manifestations, including hepatobiliary complications. This prospective study **aimed** to assess the prevalence of hepatic manifestations and associated risk factors in a real-world IBD cohort. **Materials and methods**: Between December 2023 and March 2024, 153 patients (78 with ulcerative colitis and 75 with Crohn's disease) were enrolled at a tertiary care center in northeast Romania. Comprehensive clinical evaluations, laboratory assessments, abdominal ultrasound, and vibration-controlled transient elastography with controlled attenuation parameter (CAP) were performed. **Results:** Hepatobiliary abnormalities were identified in 43.1% of patients, with steatotic liver disease (SLD) being the most common manifestation (26.8%). Notably, SLD was observed in 30.8% of ulcerative colitis and 22.7% of Crohn's disease patients. Patients with hepatic manifestations exhibited higher inflammatory markers (white blood cell count, C-reactive protein), liver enzymes, CAP values, and fibrosis, alongside longer disease duration and increased flare frequency. Multivariate analysis revealed that older age, higher body mass index, a diagnosis of Crohn's disease, and elevated CRP levels were independent predictors of hepatic involvement. **Conclusions:** These findings underscore the importance of routine liver screening and integrated hepatologic assessment in IBD management to address potential complications and improve patient outcomes. **Keywords:** INFLAMMATORY BOWEL DISEASE, HEPATIC MANIFESTATIONS, STEATOTIC LIVER DISEASE, LIVER INJURY.

INTRODUCTION

Inflammatory bowel disease (IBD) is a digestive disease with multisystemic involvement. Extraintestinal manifestations of IBD are common, occurring in both ulcerative colitis (UC) and Crohn's disease (CD), and significantly affect patient morbidity and mortality (1). Approximately 5%

of IBD patients will develop chronic liver disease, whereas up to 30% of IBD patients will have aberrant liver findings. The etiology of hepatic manifestations linked to IBD remains unclear; nevertheless, the relationship between the two conditions may be affected by immunological, genetic, and environmental variables (2). IBD progression and its complications and extraintestinal manifestations are of great interest with an important impact on the quality of life of these patients.

Fatty liver, or steatotic liver disease, represents the most prevalent hepatobiliary disorders of IBD. Its progression is directly attributable to obesity, insulin resistance, and metabolic syndrome, which is currently regarded as the hepatic manifestation of metabolic syndrome. The clinical and histological spectrum is broad, encompassing simple steatosis, steatohepatitis, nonalcoholic steatohepatitis (NASH), liver cirrhosis, and hepatocellular carcinoma. According to research, people with IBD are more likely to develop NAFLD due to chronic inflammation, digestive abnormalities, prior surgery, and changes in the fecal microbiota. The prevalence appears to be at least comparable to or greater than in the general population, current data indicates a prevalence between 8% and 71% (3, 4). Moreover, lean individuals, a feature often presented in IBD patients, are mostly overlooked representing a diagnosis challenge due to their normal BMI.

In 2023, liver disease experts introduced Steatotic Liver Disease (SLD) as a new umbrella term for conditions involving fat accumulation in the liver, replacing the older “fatty liver disease” label. Within this framework, NAFLD has been renamed Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD). This shift aims to reduce stigma tied to terms like “non-alcoholic” and better reflect the disease’s connection to metabolic issues such as obesity and diabetes. MASLD requires evidence of hepatic steatosis plus at least one metabolic risk factor. A notable addition is Metabolic and Alcohol-Associated Liver Disease (MetALD), a category for MASLD patients who also consume moderate alcohol. This change, driven by major liver associations, enhances classification accuracy and encourages a more inclusive, patient-focused approach to liver health (5-7).

Primary sclerosing cholangitis (PSC) is strongly associated with IBD, particularly UC. In the Caucasian population, it is estimated that 4% of UC patients may develop PSC, and three-quarters of PSC patients have UC (8). Cholelithiasis is also a frequent pathology found in patients with IBD. Individuals with Crohn's disease are twice as likely to develop gallstones. In contrast, patients with UC do not have an elevated risk compared with the general population. (9, 10). Cholelithiasis, granulomatous hepatitis, portal vein thrombosis, IgG4-related cholangiopathy, pyogenic liver abscess, hepatic amyloidosis, and PSC are occurring IBD-related hepatobiliary manifestations (11, 12).

In recent decades, therapeutic options for the management of IBD have expanded. New biological and small molecule therapies have been incorporated into the pharmacological arsenal, allowing for a more individualized approach and the pursuit of ever-stricter remission targets. Drug induced liver injury (DILI) in an IBD patient may present with elevated alanine aminotransferase (ALT) and aspartate aminotransferase (AST); alkaline phosphatase (ALP) and gamma-glutamyl transferase

(GGT) (cholestasis pattern); jaundice (hyperbilirubinemia); or a combined pattern. This complication can occur acutely with the development of acute liver failure, autoimmune hepatitis, and reactivation of hepatitis B, and some of these patients may develop chronic injury (13).

Hepatitis B virus reactivation is another issue that can be seen in patients with IBD. Anti-TNF and anti-integrin therapies have been linked to the reactivation of hepatitis B virus, especially in individuals who are positive for hepatitis B surface antigen (HBsAg), similar to other immunosuppressive treatments, such as prolonged or high-dose corticosteroid use. The frequency of hepatitis C virus (HCV) infection in patients with IBD seems to be lower than expected. The data suggests that IBD patients in Western European countries are no longer considered a risk category for HBV or HCV infection (14, 15).

The aim of this study was to assess the prevalence of hepatic manifestations and factors associated with their development in a real-world cohort of IBD patients.

MATERIALS AND METHODS

Between December 2023 and March 2024, we prospectively enrolled 153 patients with a confirmed diagnosis of IBD at a tertiary care center in northeast Romania. The study aimed to comprehensively assess these patients, capturing detailed personal medical histories that included detailed IBD features like duration or time of diagnosis, disease complications, extraintestinal manifestations, hepatic manifestations, and comorbidities. Each participant underwent a meticulous clinical examination, and blood samples were collected for extensive laboratory analysis. To evaluate alcohol consumption, we administered the Alcohol Use Disorders Identification Test (AUDIT) questionnaire, a validated tool for identifying potential alcohol abuse. Additionally, all patients received abdominal ultrasound and FibroScan examinations, conducted by an experienced physician.

Vibration-controlled transient elastography (VCTE) with controlled attenuation parameter (CAP) was performed using FibroScan® 502 Touch device (EchoSens, Paris, France). To ensure measurement accuracy, patients fasted for at least four hours prior to the procedure, as food intake can temporarily influence liver fat readings. The examination began with the standard M probe, switching to the XL probe when prompted by the device—typically for patients with greater body mass or thicker skin layers. The transducer was positioned in the 9th to 11th intercostal space, aligning with the right hepatic lobe, a standard site for liver assessment. SLD was diagnosed when CAP values exceeded 248 dB/m, a threshold supported by prior research (16), indicating significant fat accumulation in the liver.

This study was approved by the Ethics Committee of our University and was conducted according to the principles of the Declaration of Helsinki. Each participant signed a written informed consent form.

Statistical analyses were conducted using IBM *SPSS version 22.0* (IBM SPSS Inc., Chicago, IL, USA). Normality of numerical variables was evaluated using the Kolmogorov-Smirnov test. Normally distributed continuous variables were summarized as mean ± standard deviation, while non-normally distributed variables were expressed using medians and interquartile ranges. Categorical data were presented as frequencies and percentages. For group comparisons, parametric tests (e.g., Student's t-test for inde-

pendent samples) were applied to normally distributed continuous variables, whereas non-parametric alternatives (Mann-Whitney U or Kruskal-Wallis tests) were used for skewed distributions. Associations between categorical variables were examined using chi-square or Fisher's exact tests. Statistical significance was defined as a two-tailed *p*-value <0.05. Univariate and multivariate linear regression were performed to identify variables significantly associated with the presence of hepatic manifestations. Only complete datasets were included in the final analysis.

RESULTS

Study of population characteristics

The study cohort consisted of 153 patients diagnosed with IBD, including 78 patients with UC and 75 patients with CD. Detailed demographic and clinical characteristics are summarized in first table. The mean age was comparable between the UC and CD groups (47.8 ± 16.2 years *vs.* 47.1 ± 15.9 years, p=0.792), indicating no significant age difference. Gender distribution was also similar, with females comprising 44.9% of UC patients and 46.7% of CD patients (p=0.822). Rural residence was reported in 47.4% of UC patients and 46.7% of CD patients (p=0.924). Body mass index (BMI) showed no significant difference between groups, with means of 25.5 ± 4.1 kg/m² for UC and 25.3 ± 4.0 kg/m² for CD (p=0.788). Smoking status was assessed categorically: current smokers accounted for 35.9% of UC patients and 42.7% of CD patients, while former smokers comprised 14.1% and 12.0%, respectively, with no significant difference (p=0.751) (tab. I).

TABLE I.

Study of population characteristics

Characteristics	Ulcerative Colitis (n=78)	Crohn's Disease (n=75)	p-value
Demographics			
Age, years, mean (SD)	47.8 ±16.2	47.1 ± 15.9	0.792
Female, (%)	44.9% (35/78)	46.7% (35/75)	0.822
Rural residence, (%)	47.4% (37/78)	46.7% (35/75)	0.924
BMI, kg/m², mean (SD)	25.5 ±4.1	25.3± 4.0	0.788
Smoking status, (%)			
Current smoker, (%)	35.9% (28/78)	42.7% (32/75)	0.251
Former smoker, (%)	14.1% (11/78)	12.0% (9/75)	0.457
Disease Activity			
Active disease, %	7.7% (6/78)	2.7% (2/75)	0.277
Number of flare-ups, mean (SD)	1.6 (1.0)	1.7 (1.1)	0.513
New cases, (%)	11.5% (9/78)	6.7% (5/75)	0.315
Treatment Characteristics			
On any biologic therapy, (%)	24.4% (19/78)	36.0% (27/75)	0.115
On azathioprine, (%)	15.4% (12/78)	14.7% (11/75)	0.904
On mesalazine, (%)	76.9% (60/78)	36.0% (27/75)	<0.001
Current corticosteroid use, (%)	12.8% (10/78)	14.7% (11/75)	0.739
Number of corticosteroids courses in past year, mean (SD)	0.7 (1.2)	0.8 (1.3)	0.614

BMI: body mass index; SD: standard deviation.

Regarding disease activity, active disease was observed in 7.7% of UC patients and 2.7% (2/75) of CD patients (p=0.277). The mean number of flare-ups was 1.6 ± 1.0 in UC and 1.7 ± 1.1 in CD (p=0.513), and new cases were identified in 11.5% (9/78) of UC patients and 6.7% of CD patients (p=0.315), with no statistically significant differences across these parameters.

Treatment characteristics revealed notable differences in medication use. A significantly higher proportion of UC patients were receiving mesalazine compared to CD patients (76.9% *vs.* 36.0%, p<0.001). In contrast, the use of biologic therapy (24.4% *vs.* 36.0%, p=0.115), azathioprine (15.4% *vs.* 14.7%, p=0.904), current corticosteroids (12.8% *vs.* 14.7%, p=0.739), and the mean number of corticosteroid courses in the past year (0.7 ± 1.2 *vs.* 0.8 ± 1.3, p=0.614) showed no significant differences between UC and CD patients.

Disease-Specific characteristics

Disease-specific characteristics for UC and CD are presented in second table. Among UC patients, disease extent was categorized as proctitis (E1) in 25.6%, left-sided colitis (E2) in 28.2%, and pancolitis in 46.2%. For CD patients, age at diagnosis was distributed as follows: ≤16 years (A1) in 12.0%, 17-40 years (A2) in 65.3%, and >40 years (A3) in 22.7%. Disease location in CD was ileal (L1) in 34.7%, colonic (L2) in 28.0%, ileocolonic (L3) in 37.3%, and upper gastrointestinal (L4) in 6.7%. Behavioral classification revealed non-stricturing, non-penetrating (B1) disease in 70.7%, stricturing (B2) in 16.0%, and penetrating (B3) in 13.3%. Additionally, perianal disease was present in 14.7% of CD patients, with active fistulas noted in 6.7%.

TABLE II.
Disease characteristics

Ulcerative Colitis Subtypes (n=78)	
Subtype	
Proctitis (E1)	25.6% (20/78)
Left-sided colitis (E2)	28.2% (22/78)
Pancolitis (E3)	46.2% (36/78)
Crohn's Disease Classifications (n=75)	
Characteristic	
Age at Diagnosis	
A1 (≤16 years)	12.0% (9/75)
A2 (17-40 years)	65.3% (49/75)
A3 (>40 years)	22.7% (17/75)
Location	
L1 (ileal)	34.7% (26/75)
L2 (colonic)	28.0% (21/75)
L3 (ileocolonic)	37.3% (28/75)
L4 (upper GI)	6.7% (5/75)
Behavior	
B1 (non-stricturing, non-penetrating)	70.7% (53/75)
B2 (stricturing)	16.0% (12/75)
B3 (penetrating)	13.3% (10/75)
Perianal Disease	14.7% (11/75)
Active Fistulas	6.7% (5/75)

Prevalence of Hepatic Manifestations in IBD Patients

Hepatic manifestations were identified in 43.1% (66 patients) of the study cohort. The prevalence and types of hepatic manifestations are detailed in table III. Overall, SLD was the most common hepatic manifestation, affecting 26.8% of patients, followed by cholestasis in 5.88%, primary biliary cholangitis in 3.27%, occult hepatitis B virus (HBV) infection in 1.96%, hepatitis B virus infection in 1.3%, and hepatitis C virus infection in 0.65%.

When stratified by IBD type, SLD remained the predominant hepatic manifestation in both UC (30.77%) and CD (22.66%). However, differences emerged in other manifestations: cholestasis was more prevalent in CD (10.66%) than in UC (1.28%), while PSC was more frequent in UC (5.13%) than in CD (1.33%). Autoimmune hepatitis was exclusive to CD patients (4%), whereas hepatitis B virus infection was observed only in UC patients (2.56%). DILI was noted only in the personal history of 3 patients. At the time of inclusion in the study none of the patients had criteria for the diagnosis of DILI.

TABLE III.
Prevalence of hepatic manifestations

Hepatic Manifestation	Overall Cohort (N=153)	Ulcerative Colitis (N=78)	Crohn's Disease (N=75)
Primary biliary cholangitis	5 (3.27 %)	4 (5.13 %)	1 (1.33 %)
Cholestasis	9 (5.88 %)	1 (1.28 %)	8 (10.66 %)
DILI	3 (1.96 %)	2 (2.56 %)	1 (1.33 %)
Autoimmune hepatitis	3 (1.96 %)	0	3 (4 %)
Hepatitis C virus infection	1 (0.65 %)	0	1 (1.33 %)
Hepatitis B virus infection	2 (1.3 %)	2 (2.56 %)	0
Occult hepatitis B virus infection	3 (1.96 %)	2 (2.56 %)	1 (1.33 %)
SLD	41 (26.8%)	24 (30.77 %)	17 (22.66 %)

DILI: drug induced liver injury; SLD: steatotic liver disease

Comparison of Patients with and without Hepatic Manifestations

Patients with hepatic manifestations (n=66) were compared to those without (n=87) (tab. IV). Demographic and anthropometric parameters, including age, weight, height, BMI, CUN-BAE and sex distribution, showed no significant differences between the groups. However, significant differences were observed in several laboratory and clinical parameters. Patients with hepatic manifestations exhibited higher white blood cell counts (p=0.001), CRP levels (p=0.031), ALT (p=0.01), GGT (p=0.02), fecal calprotectin (p=0.01), triglycerides (p=0.012), CAP values (p=0.005) and fibrosis (p=0.001). Additionally, these patients had a longer disease duration (p=0.022), a higher number of flare-ups (p=0.023), and a greater prevalence of extraintestinal manifestations (excluding hepatic) (p=0.002). No significant differences were noted in hemoglobin, platelets, AST, ALP, total bilirubin, albumin, cholesterol, or previous surgical interventions.

TABLE IV.
Comparison of patients with and without hepatic manifestations

Parameter	Patients with Hepatic Manifestations N=66 (43.1%)	Patients Without Hepatic Manifestations N=87 (57.9%)	p-value
Age (years)	47.23±8.5	46.67±9.1	0.86
Weight (kg)	76.87±12.3	72.02±10.8	0.14
Height (cm)	171.87±6.2	170.84±5.9	0.53
BMI (kg/m²)	25.95±4.5	24.61±3.2	0.17
CUN-BAE	30.5±8.9	28.7±5.9	0.23
Sex (% Female)	43.33%	43.09%	0.98
White Blood Cells (x10³/μL)	7.82±1.5	5.82±1.2	0.001
Hemoglobin (g/dL)	13.45±1.2	13.42±1.1	0.93
Platelets (x10³/μL)	288.60±45.3	310.62±50.1	0.23
CRP (mg/L)	1.38±1.1	0.66±0.8	0.031

GGT (U/L)	70.87±25.6	43.93±18.2	0.02
ALP (U/L)	105.27±30.2	88.33±25.7	0.07
Total Bilirubin (mg/dL)	0.82±0.3	0.62±0.2	0.06
Albumin (g/dL)	4.20±1.21	4.36±1.35	0.15
Calprotectin (μg/g)	266±58	153±41	0.01
Cholesterol (mg/dL)	224±28.3	192±18.7	0.35
Triglycerides (mg/dL)	172±15.2	112±10.5	0.012
CAP values (dB/m)	285±22	243±32	0.005
Fibrosis (kPa)	8.5±2.3	5.2±1.3	0.001
Hypertension	13.2%	10.1%	0.43
T2DM	15.5%	12.2%	0.56
Disease Duration (years)	8.37±2.5	4.02±3.1	0.022
Number of Flares	3.73±0.9	1.67±0.8	0.023
Previous Surgical Interventions	26.6%	17.6%	0.11
Extraintestinal Manifestations (excluding hepatic manifestations)	32.30%	8.13%	0.002

BMI: body mass index; CAP: controlled attenuation parameter; ALT: alanine aminotransferase; AST: aspartate aminotransferase; GGT: gamma-glutamyl transferase; ALP: alkaline phosphatase; CRP, c-reactive protein; T2DM, Type 2 diabetes; CUN-BAE, Clínica Universidad de Navarra-Body Adiposity Estimator.

Risk Factors for Hepatic Manifestations

Univariate and multivariate logistic regression analyses were conducted to identify risk factors associated with hepatic manifestations (tab. V). In the univariate analysis, significant associations were found with older age (odds ratio [OR]=1.05, 95% confidence interval [CI]: 1.01–1.09, p=0.02), higher BMI (OR=1.10, 95% CI: 1.02–1.18, p=0.01), Crohn's disease diagnosis (OR=2.5, 95% CI: 1.20–5.20, p=0.01), elevated CRP (OR=1.02, 95% CI: 1.21–2.9, p=0.01), female sex (OR=1.8, 95% CI: 1.05–3.10, p=0.04), current smoking (OR=2.1, 95% CI: 1.10–4.00, p=0.03), infliximab use (OR=2.0, 95% CI: 1.05–3.80, p=0.04), and hypertension (OR=1.9, 95% CI: 1.05–3.50, p=0.03).

In the multivariate analysis, independent risk factors for hepatic manifestations included older age (OR=1.17 per year, 95% CI: 1.00–2.08, p=0.03), higher BMI (OR=1.08 per kg/m², 95% CI: 1.01–1.15, p=0.02), Crohn's disease (OR=2.2, 95% CI: 1.05–4.60, p=0.01), and elevated CRP (OR=1.11, 95% CI: 1.00–1.24, p=0.04). Female sex, CRP level, current smoking, infliximab use, and hypertension did not retain significance in the multivariate model.

TABLE V.

Univariate and multivariate analysis of factors associated with development of hepatic manifestations in IBD patients

Variable	Univariate OR (95% CI)	Univariate p-value	Multivariate OR (95% CI)	Multivariate p-value
Age (years)	1.05 (1.01-1.09)	0.02	1.17 (1.00-2.08)	0.03
BMI (kg/m²)	1.10 (1.02-1.18)	0.01	1.08 (1.01-1.15)	0.02
Crohn's Disease	2.5 (1.20-5.20)	0.01	2.2 (1.05-4.60)	0.01
CRP (mg/dL)	1.02 (1.21-2.9)	0.01	1.11 (1.00-1.24)	0.04
Female Sex	1.8 (1.05-3.10)	0.04	1.5 (0.80-2.80)	0.20
Current Smoker	2.1 (1.10-4.00)	0.03	1.7 (0.85-3.40)	0.13
Infliximab Use	2.0 (1.05-3.80)	0.04	1.6 (0.75-3.40)	0.22
Hypertension	1.9 (1.05-3.50)	0.03	1.4 (0.70-2.80)	0.34

BMI: body mass index; CRP: c-reactive protein

Lean SLD subgroup analysis

A special subgroup of patients in our data set are those with normal BMI, accounting for 73 individuals, with 26 of them having SLD. The mean age of lean IBD patients with SLD was significantly higher than that of those without SLD (54.2 ± 12.3 years *vs.* 45.6 ± 10.8 years, p = 0.002). Gender distribution also differed, with a higher proportion of males in the SLD group compared to the non-SLD group (60% *vs.* 45%, p = 0.045). Residence distribution (urban *vs.* rural) showed no significant difference between the two groups (p = 0.321). Disease duration was longer in the SLD group (12.5 ± 6.7 years *vs.* 8.3 ± 5.2 years, p = 0.004), and the mean number of flare-ups was greater (3.2 ± 1.5 *vs.* 2.1 ± 1.2, p = 0.001). Disease activity scores were also elevated in the

SLD group, with ulcerative colitis (UC) patients showing a higher mean Mayo score (6.8 ± 2.1 *vs.* 4.5 ± 1.9, p = 0.003) and CD patients demonstrating a higher mean Crohn's Disease Activity Index (CDAI) (220 ± 50 *vs.* 180 ± 45, p = 0.007). Regarding treatment options, a greater percentage of patients with SLD were treated with biologics (55% *vs.* 40%, p = 0.028) and immunomodulators (45% *vs.* 30%, p = 0.041) compared to those without SLD. Corticosteroid use was more common in the SLD group, though the difference was not statistically significant (35% *vs.* 25%, p = 0.112).

Significant differences were observed in laboratory parameters between the two groups. Patients with SLD had higher mean C-reactive protein (CRP) levels (15.4 ± 7.2 mg/L *vs.* 10.2 ± 5.6 mg/L, p = 0.001) and elevated liver enzymes, including alanine aminotransferase (ALT) (45 ± 15 U/L *vs.* 25 ± 10 U/L, p < 0.001), aspartate aminotransferase (AST) (40 ± 12 U/L *vs.* 22 ± 8 U/L, p < 0.001), and gamma-glutamyl transferase (GGT) (55 ± 20 U/L *vs.* 30 ± 12 U/L, p < 0.001). Lipid profiles revealed higher mean total cholesterol (210 ± 35 mg/dL *vs.* 180 ± 30 mg/dL, p = 0.004) and triglycerides (150 ± 40 mg/dL *vs.* 120 ± 35 mg/dL, p = 0.012) in the SLD group, alongside lower high-density lipoprotein (HDL) levels (40 ± 10 mg/dL *vs.* 50 ± 12 mg/dL, p = 0.008). Moreover, metabolic abnormalities, such as abnormal glucose levels, were also more prevalent in the SLD group (25% *vs.* 15%, p = 0.048).

DISCUSSION

Our study highlights that nearly half (43.1%) of patients with IBD exhibit some form of hepatic manifestation, with SLD being the most common finding. This high prevalence reinforces the notion that hepatic involvement is a frequent extraintestinal feature of IBD, as previously documented (17,18). The prevalence of hepatic manifestations in our cohort is notably higher than the pooled prevalence of extraintestinal manifestations reported by Kilic *et al.*, which stood at 31.3% across IBD patients globally (1). Hepatobiliary manifestations constitute a significant subset of extraintestinal manifestations, and our elevated prevalence may reflect the meticulous diagnostic approach employed, including the use of FibroScan. This advanced tool likely enhanced the detection of subclinical liver abnormalities, such as early steatosis or fibrosis, which might be missed by conventional methods like ultrasound alone. This aligns with findings by Veltkamp *et al.*, who emphasized the utility of non-invasive tools in identifying hepatic steatosis and fibrosis in IBD patients (2).

The prevalence of SLD is 26.8% in our cohort (30.77% in UC and 22.66% in CD), and is the dominant hepatic manifestation, consistent with the growing recognition of MASLD as a common comorbidity in IBD. The prevalence aligns with findings by Sartini *et al.*, who reported a 28% prevalence of NAFLD in IBD patients, emphasizing the role of metabolic risk factors (19). Another recent study reported that 25% of IBD patients had MASLD, with higher rates in those with obesity and insulin resistance, supporting our observation of BMI as a risk factor (20).

An intriguing finding is the association of hepatic manifestations with CD rather than UC, with CD identified as an independent risk factor (OR=2.2, 95% CI: 1.05–4.60, p=0.01). Results from current

literature are heterogenous. A study that compared the two conditions reported that CD patients had a higher prevalence of hepatic steatosis compared to UC patients, possibly due to metabolic factors like BMI (21). One more recent study found that CD patients had a higher risk of gallstones and hepatic steatosis, linked to ileal dysfunction and chronic inflammation (22). Of note is the fact that the prominence of CD as a risk factor may reflect its association with metabolic factors, which are more pronounced in CD patients due to malabsorption or chronic inflammation altering metabolic profiles, results similar with other studies (23).

Patients with hepatic manifestations exhibited elevated white blood cell counts, CRP, ALT, GGT, fecal calprotectin, triglycerides, longer disease duration, and more flare-ups. These markers indicate active inflammation and metabolic dysfunction, reinforcing the interplay between IBD activity and liver health. The association between longer disease duration and hepatic manifestations is consistent with the findings from literature in which IBD patients with longer disease duration are more likely to develop MASLD (24).

Multivariate analysis identified older age (OR=1.17 per year, p=0.03), higher BMI (OR=1.08 per kg/m², p=0.02), CD (OR=2.2, p=0.01), and elevated CRP (OR=1.11, p=0.04) as independent predictors of hepatic manifestations. These findings are supported by results from a recent meta-analysis showing that MASLD significantly impacts clinical outcomes in patients with metabolic risk factors (25). Elevated CRP, a marker of systemic inflammation, supports the hypothesis that chronic inflammation in IBD contributes to liver pathology, being involved in the progression of NAFLD (26).

The interplay between immunosuppressive therapies and liver injury also warrants careful consideration. Although DILI was documented only in a small number of patients in our study, its occurrence is clinically significant given the expanding therapeutic armamentarium for IBD management (12).

Our cohort revealed that lean IBD patients with SLD were significantly older than those without SLD (p = 0.002). This observation aligns with findings from the general MASLD population, where age is a recognized risk factor for disease progression. For example, Unger *et al*. (2020) reported that older age was associated with a higher prevalence of hepatic steatosis in lean patients, irrespective of underlying conditions (27). Moreover, a higher prevalence of Crohn's disease (CD) among lean IBD patients with SLD (65% *vs.* 50%, p = 0.031) was observed, suggesting a specific association between CD and liver steatosis, results that are in line with data from current literature (28). Additionally, our SLD group exhibited longer IBD duration and greater disease activity. These results parallel those of Sartini *et al.*, who demonstrated that prolonged IBD activity increases the risk of liver steatosis, emphasizing chronic inflammation's role in MASLD pathogenesis (19). The consistency with prior studies underscores the interplay between IBD severity and liver involvement in lean patients.

Although this study provides significant insights into the epidemiology and risk variables associated with hepatic symptoms in IBD, it also possesses limitations. The single-center design and limited sample

size may constrain the generalizability of the results. Future multicenter studies with bigger cohorts and longitudinal follow-up are essential to clarify the natural history of hepatic involvement in IBD and to enhance therapy methods.

CONCLUSIONS

In conclusion, the high prevalence of hepatic manifestations, particularly SLD, among IBD patients calls for routine liver screening and a proactive management strategy. Our findings advocate for the integration of hepatologic assessment into the standard care of IBD patients, which may ultimately improve clinical outcomes by mitigating the impact of these extraintestinal complications.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflicts of interests. The research did not receive external funding.

THE IMPACT OF BARIATRIC SURGERY ON CORTISOL AND OXYTOCIN IN OBESE PATIENTS (Abstract): Morbid obesity is linked to widespread endocrine dysregulation, including heightened stress and responses and altered social-bunding signals. Cortisol, the primary effector of the hypothalamic-pituitary-adrenal (HPA) axis, drives insulin resistance and systemic inflammation, while oxytocin, a hypothalamic neuropeptide, influences appetite control, emotional coping and social behaviors. Although bariatric surgery is stablished as the most effective long-term treatment for severe obesity, its impact on these two pivotal hormones remains incompletely defined. **Aim:** To evaluate and compare plasma samples of cortisol and oxytocin concentrations in adults with morbid obesity before and three months after bariatric surgery, relative to healthy non-obese controls. **Materials and methods:** In this prospective longitudinal study, we enrolled 21 patients (age 25-60 years; Body Mass Index (BMI) $\geq$ 40 kg/m^2) scheduled for either sleeve gastrectomy or Roux-en-Y gastric bypass, alongside 10 healthy volunteers (BMI 22 $\pm$ 1 kg/m^2). Fasting blood samples were drawn on the morning surgery (T0) and at a three-month follow-up visit (T2). Plasma cortisol and oxytocin levels were quantified via high-sensitivity competitive immunoassays. Repeated-measures analyses compared hormonal shifts within the surgical cohort and against controls. **Results:** At baseline, patients exhibited markedly elevated cortisol (86.6 $\pm$ 50.2 ng/mL) and oxytocin (553 $\pm$ 115 pg/mL) compared with controls (54.3 $\pm$ 40.1 ng/mL and 380 $\pm$ 100 pg/mL, respectively). Three months following surgery, mean cortisol declined by 66% to 29.5 $\pm$ 22.4 ng/mL ($p < 0.001$), approximating control values, whereas oxytocin decreased modestly to 483 $\pm$ 120 pg/mL ($p = 0.02$), indicating partial normalization. The magnitude of cortisol reduction correlated strongly with the degree of weight loss and oxytocin adjustment aligned with patient-reported improvements in psychological well-being. **Conclusions:** Bariatric surgery elicits rapid and significant recalibration of both stress-related and social-bonding hormonal axes. The pronounced cortisol decreases and the trend toward normalized oxytocin suggest dual benefits, metabolic and psychological, in the early postoperative period. These findings support integrating targeted nutritional and psychological interventions to

reinforce endocrine recovery and enhance long-term surgical outcomes. **Keywords:** BARIATRIC SURGERY, CORTISOL, OXYTOCIN, MORBID OBESITY, STRESS HORMONES, SOCIAL BONDING, IMMUNOASSAY.

INTRODUCTION

Obesity is a complex, chronic disease characterized by excess adiposity and associated with elevated risk of cardiovascular disease, type 2 diabetes and decreased life expectancy (Rutters *et al*., 2012). Bariatric surgery has emerged as the most effective intervention for achieving sustained weight loss and metabolic improvement in individuals with severe obesity, with procedures such as sleeve gastrectomy and Roux-en-y gastric bypass demonstrating durable benefits over medical therapy alone (Bando *et al*., 2023). Beyond reductions in body mass index, these surgical approaches elicit profound alterations in glucose homeostasis, gut hormone secretion and energy expenditure, suggesting mechanisms that extend beyond simple caloric restrictions (Cornejo-Pareja *et al*., 2019).

Except adipose tissue promotes dysregulations of the hypothalamic-pituitary-adrenal (HPA) axis, leading to elevated cortisol secretion that contributes to visceral fat accumulation and insulin resistance (Bose *et al*., 2009). Chronically increased cortisol levels exacerbate systemic inflammation and impair lipid metabolism, thereby reinforcing the cycle of metabolic dysfunction in obesity (Incollingo Rodriguez *et al*., 2015). Several studies have documented normalization of both basal and postprandial cortisol concentrations following bariatric surgery, reflecting restoration of HPA axis homeostasis; however, the magnitude and time course of these changes vary according to the type of surgical procedure and the postoperative interval examined (Casteràs *et al*., 2024; Cornejo-Pareja *et al*., 2019).

Oxytocin, a neuropeptide synthetized in the hypothalamus, plays key roles in social bonding, stress modulation and the regulation of appetite and energy balance (Lawson, 2017). Circulating oxytocin levels have been reported to be elevated in individuals with morbid obesity compared to lean controls, though these levels may decline following substantial weight-loss interventions (Pataky *et al*., 2019). Preclinical and early clinical trials indicate that oxytocin administration enhance lipolysis, increases fatty acids oxidation and supports lean mass preservation, independent of reductions in food intake (Kerem *et al*., 2021). Nevertheless, the literature on post-bariatric changes in endogenous oxytocin is mixed with some cohorts showing significant decreases at 12 months after sleeve gastrectomy and others reporting stable levels despite marked weight-loss (Becetti *et al*., 2023; Pataky *et al*., 2019).

Given the central roles of cortisol and oxytocin in coordinating metabolic and psychosocial adaptations, elucidating their joint response to bariatric surgery may uncover insights into both the psychological and behavioral drivers of postoperative recovery. In this longitudinal comparative study, we evaluate plasma samples of cortisol and oxytocin before and three months after bariatric intervention in patients with morbid obesity, benchmarking these changes against healthy controls to advance understanding of endocrine remodeling in the early post-surgical period.

MATERIALS AND METHODS

We conducted a prospective study with 21 patients diagnosed with morbid obesity (BMI ≥ 40 kg/m^2), all undergoing bariatric surgery in the 3rd Department of Surgery of the "St. Spiridon" Hospital in Iasi, Romania. Of these, seven patients underwent laparoscopic sleeve gastrectomy and the remaining fourteen underwent Roux-en-Y gastric bypass. As a reference group, we included ten normal-weight adults (mean BMI 22 ± 1 kg/m^2), aged between 30 and 35 years, without metabolic comorbidities.

For enrollment in the obesity cohort, the following were required> BMI at least 40 kg/m^2, recommendation for bariatric surgery, age between 21 and 65 years and written informed consent. The volunteers in the control group were not chronic alcohol users, did not have active infectious disease and were not taking vitamin supplements, maintaining their usual medication regimen until the day of collection.

Excluded from both groups were people using antioxidants or anti-inflammatory treatments, those with a recent history of trauma or surgery (last six months), pregnant or lactating women and those engaged in restrictive diets (ketogenic, vegan, etc.) that could have affected hormonal levels. All blood samples were collected in the morning, before launch, both for the initial assessment and for the three-month control. Plasma separated by centrifugation was stored at -80 ° and analyzed in duplicate for cortisol and oxytocin, and the values were averaged for interpretation.

Cortisol Determination

Plasma cortisol was analyzed using a competitive ELISA kit (Fine Test, China) at 1:20 dilution. Optical density was read at 450 nm, with a standard curve spanning 0.0391-25 ng/mL (S1-S7) and a zero-concentration control (S8). Intra and inter-assay variability were < 8% (tab. I)

TABLE I.
Competitive ELISA Standard Curve for Cortisol: Optical density (450 nm) vs. Concentration (0-25 ng/mL)

Standard	OD at 450 nm	Conc. (ng/mL)
S1	0.518	25
S2	0.947	12.5
S3	1.042	6.25
S4	1.243	3.125
S5	1.65	1.562
S6	1.954	0.781
S7	2.115	0.391
S8	2.54	0

Figure 1 depicts a competitive ELISA standard curve for cortisol, demonstrating an inverse correlation between optical density (OD = 450 nm) and cortisol concentration (0.0391-25 ng/mL), with OD value rising as hormone levels decrease. Assay precision is evidenced by low variability (<8%) and a zero-concentration control (S8) showing maximal OD (2.54), confirming analytical reliability.

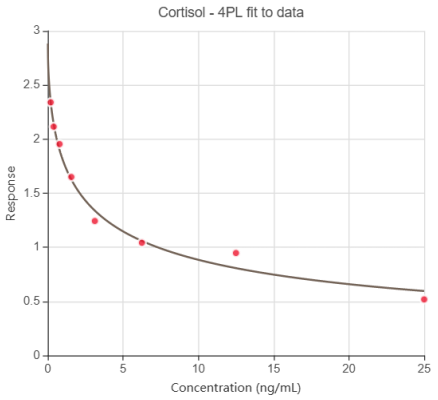

Fig. 1. Cortisol ELISA Standard Curve - Relationship between Optical Density (OD) and Concentration

Oxytocin Determination

Plasma oxytocin levels were quantified using a competitive ELISA kit (Abcam Oxytocin ELISA Kit). Serum samples underwent solid-phase extraction on C18 cartridges minimize matrix interference, followed by 1:8 dilution in assay buffer. Absorbance was measured at 405 nm with concentrations interpolated from a seven-point standard curve (15.6-1000 pg/mL; two-fold dilutions). The assay's sensitivity was 15 pg/mL with intra- and inter-assay coefficients of variation < 10% (tab. II)

TABLE II.

Competitive ELISA Standard Curve for Oxytocin (Dilution 1:8): Optical Density (OD = 405 nm) *vs.* Concentration

Standard	OD at 405 nm	Conc. (pg/mL)
S1	0.165	1000
S2	0.254	500
S3	0.373	250
S4	0.502	125
S5	0.628	62.5
S6	0.71	31.2
S7	0.758	15.6

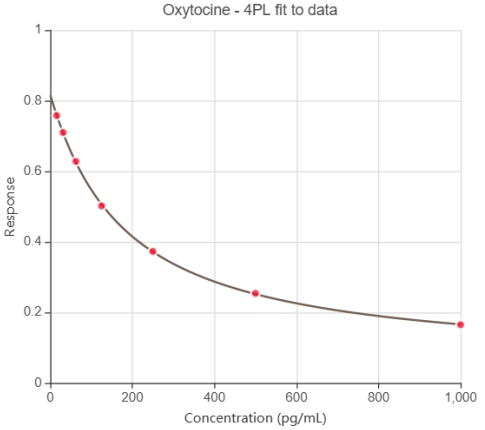

Fig. 2. Competitive ELISA Standard Curve for Oxytocin (Dilution 1:8)-Relationship between Optical Density (OD) and Concentration

Table II and figure 2 illustrates the standard ELISA curve for oxytocin (1:8 dilution), demonstrating an inverse correlation between OD at 405 nm and hormone concentration (15.6-1000 pg/mL). At maximum concentrations (1000 pg/mL), the OD is minimal (0.165), while at low concentrations (15.6 pg/mL) the OD reaches 0.758. The curve covers a wide dynamic range, suitable for the quantification oxytocin in physiological and pathological samples. The logarithmic trend line confirms the reliability of the method, with coefficients of variation below 10%.

Data Analysis. Normality of hormone distributions was assessed by the Shapiro-Wilk test. Repeated-measures analyses of variance (ANOVA) evaluated within-subject changes from T0 to T2, with post-hoc Bonferroni corrections for multiple comparisons. Independent-sample t-tests compared baseline patient values to controls. Pearson correlation coefficient quantified relationship between hormone changes and clinical parameters, including percent excess weight loss and self-reported quality of life scores. Statistical significance was defined as $p< 0.05$. Analyses were conducted using SPSS version 26.0 (IBM Corp., Armonk, NY).

Quality Control and Ethical Considerations

All reagents were lot-verified and assay runs included quality control samples covering the analytical range. Laboratory personnel were blinded to participant group and time point. The study adhered to the Declaration of Helsinki and complied with institutional guidelines for human subjects research.

RESULTS

The investigation recruited 31 participants stratified in three cohorts> a reference group of 10 metabolically healthy

individuals (mean body mass index: 22 ± 1 kg/m^2), a clinical population of 21 adults meeting criteria for severe obesity (BMI ≥ 40 kg/m^2) and an intervention subset comprising 10 surgically managed patients reevaluated 90 days post-bariatric procedure. Demographic analysis revealed pronounced gender disparity in the obese cohort, with 95.2% female representation (20 females and 1 male) and an age distribution spanning young adulthood to senior years (21-65 years). These obese group exhibited a high burden of chronic metabolic and cardiovascular comorbidities, notably insulin resistant diabetes, persistent hypertension and reflux pathology. Pharmacotherapeutic patterns indicated prevalent use of glucose-modulating agents, gastric acid suppressants, thyroid hormone replacements and cardio-selective β-adrenergic antagonists. Postprocedural monitoring documented clinically significant anthropometric improvements, with mean BMI declining from 50.5 kg/m^2 (± 6.3) preoperatively to 39.0 kg/m^2 (± 7.6), reflecting pronounced early-phase weight reduction following surgical intervention.

Hormonal Dynamics:

Cortisol and Oxytocin

Cortisol Levels Across Groups

At baseline, patients with morbid obesity exhibited elevated fasting serum cortisol levels (86.6 ± 50.2 ng/mL) compared to the control group (54.3 ± 40.1 pg/mL). Three months post-surgery, a significant reduction in cortisol levels was observed (29.5 ± 22.4 ng/mL), aligning closely with control values. Statistical analysis confirmed Baseline vs. Control: p = 0.02 and Postoperative vs. Baseline: p < 0.001. This substantial decrease suggests a normalization of HPA axis activity following weight loss induced by bariatric surgery (fig. 3).

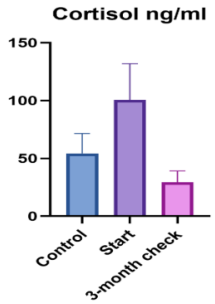

Fig. 3. Cortisol levels in control, before and after surgery

Oxytocin Levels Across Groups

Baseline oxytocin concentrations were higher in obese patients (553 ± 115 pg/mL) compared to controls (380 ± 100 pg/mL). After three months, oxytocin levels decreased to 483 ± 120 pg/mL. Comparative analyses revealed statistically significant differences between cohorts. The baseline obese group demonstrated marked divergence from healthy cohorts (p = 0.01). Postoperative evaluations showed significant anthropometric improvement relative to preoperative measures (p = 0.02), though comparison between surgically managed patients and the control group did not attain statistical significance (p = 0.15). These results indicate a partial normalization of oxytocin level post-surgery, though not fully reaching control values (fig. 4.)

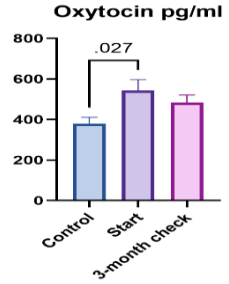

Fig. 4. Oxytocin levels in control, before and after surgery

Correlation Analyses

Age-Related Hormonal Variations

A moderate positive correlation between age and baseline cortisol levels was identified (r = 0.31) (fig. 5) suggesting increased HPA axis activity with advancing age. Postoperative reductions in cortisol were more pronounced in patients under 40 years, indicating age-related differences in hormonal adaptability (fig. 6).

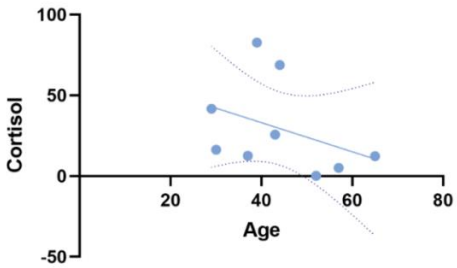

Fig. 5. Correlation between age and cortisol levels recorded preoperatively

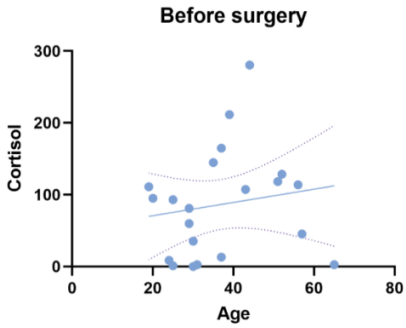

Fig. 6. Correlation between age and cortisol levels recorded postoperative

No significant correlation between age and oxytocin levels was observed at baseline (r = -0.05) (fig. 7) or postoperatively (fig. 8), implying that oxytocin dynamics are relatively age-independent in this cohort.

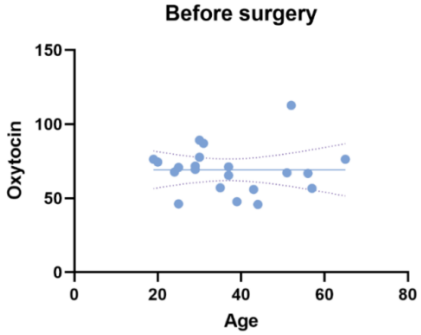

Fig. 7. Correlation between age and oxytocin levels recorded preoperatively

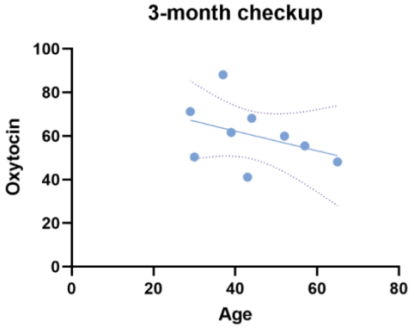

Fig. 8. Correlation between age and oxytocin levels recorded postoperatively

Weight-Related Hormonal variations

A significant positive correlation was observed between baseline body weight and serum cortisol levels (r = 0.57), indicating that individuals with higher body weight tended to have elevated cortisol concentrations. Following bariatric surgery, a notable inverse correlation emerged between the extent of weight loss and the reduction in cortisol levels (r = -0.68), suggesting that greater weight loss was associated with more substantial decreases

in cortisol. These relationships are visually depicted in figure 9 and 10, which illustrates the linear associations between body weight and cortisol levels both before and after surgical interventions.

A moderate positive correlation was observed between baseline weight and serum oxytocin levels (r = 0.49), suggesting that higher body mass may be associated with increased oxytocin secretion in the preoperative state. This association is visually illustrated in figure 11, where a trend line indicates a gradual elevation in oxytocin levels with increasing weight. The dispersion of values suggests moderate interindividual variability, yet the overall directionality supports a consistent physiological link.

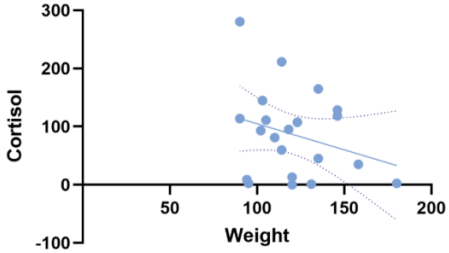

Fig. 9. Correlation between body weight and cortisol levels recorded preoperatively

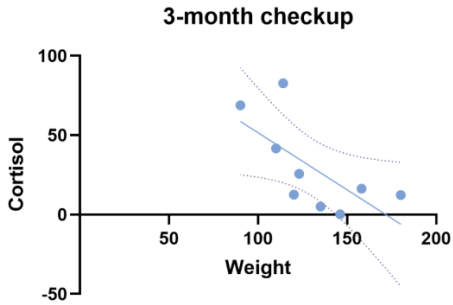

Fig. 10. Correlation between body weight and cortisol levels recorded postoperatively

Three months post-surgery, oxytocin levels decreased in most participants, and this reduction demonstrated an inverse correlation with the amount of weight lost (r = -0.42). This trend suggest that oxytocin secretion may adapt to changes in energy balance or adipose tissue mass. The postoperative association is depicted in figure 12, where a downward trend can be noticed in oxytocin values relative to reduced weight, reinforcing the hypothesis of hormonally mediated metabolic recalibration following bariatric surgery.

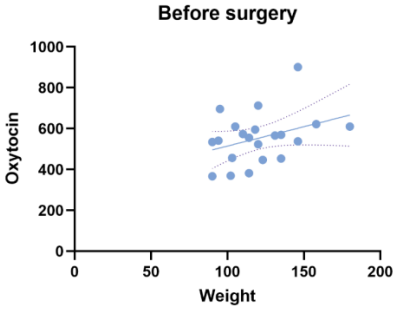

Figure 11. Correlation between body weight and oxytocin levels recorded preoperatively

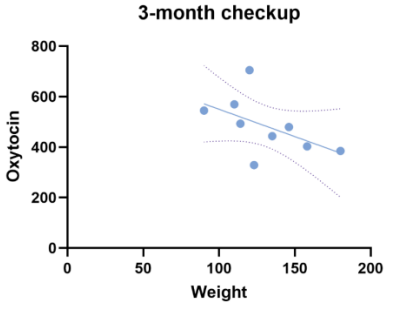

Figure 12. Correlation between body weight and oxytocin levels recorded postoperatively

BMI-Related Hormonal Variations

At baseline, BMI was positively correlated with serum cortisol levels (r = 0.51), supporting the hypothesis that adiposity contributes to elevated stress hormone secretion. Figure 13 illustrates this association where a clear upward trend can be observed: as BMI increases, cortisol levels tend to rise. This reinforces the role of excessive adipose tissue as a chronic physiological stressor.

Three months after bariatric surgery, a significant reduction in BMI was observed and this was strongly associated with a decrease in cortisol levels (r = -0.65). The inverse relationship is presented in figure 14, where lower BMI values post-surgery align with diminished cortisol secretion. This suggest a restoration of HPA axis homeostasis following weight loss and potentially a reduced allostatic load in post-bariatric patients.

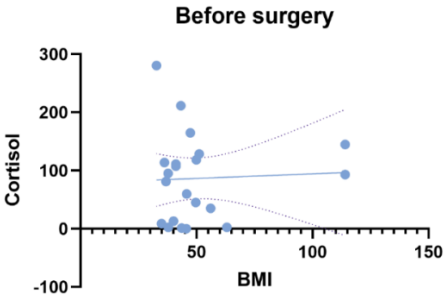

Fig. 13. Correlation between BMI and cortisol levels recorder preoperatively

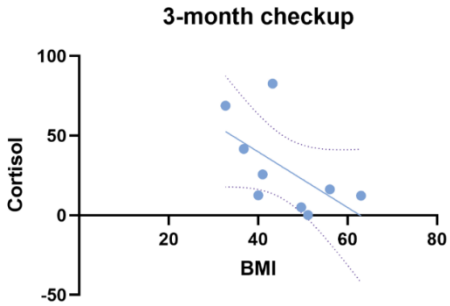

Fig. 14. Correlation between BMI and cortisol levels recorder postoperatively

Similarly, a moderate positive correlation existed between BMI and oxytocin levels prior to surgery (r = 0.46) (fig. 15). Participants with higher BMI tended to present with increased oxytocin concentrations. This could reflect a compensatory neuroendocrine mechanism, possibly modulating appetite, reward sensitivity or metabolic regulation in obesity.

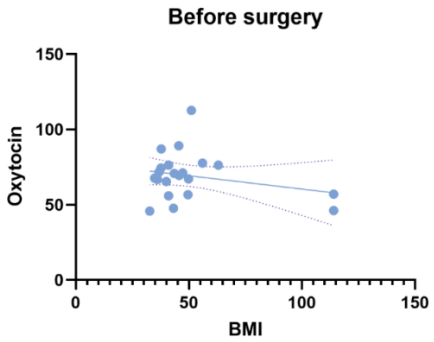

Fig. 15. Correlation between BMI and oxytocin levels recorder preoperatively

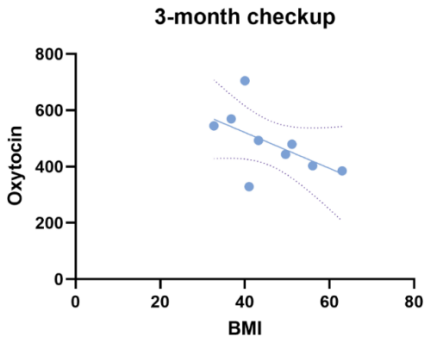

Fig. 16. Correlation between BMI and oxytocin levels recorder postoperatively

Following surgical intervention and BMI normalization, oxytocin levels shoved an inverse correlation with BMI (r= -0.39). This inverse trend suggests a potential normalization of oxytocinergic tone in relation to reduced fat mass (fig. 16). These findings contribute to the emerging understanding of oxytocin as more than a social neuropeptide, implying roles in energy metabolism and post-obesity hormonal adjustment.

Pearson correlation coefficients quantified relationship between hormonal levels and clinical parameters (weight, BMI). All analyses were two-tailed with significance set at $p < 0.05$. Data were processed using *SPSS v 26.0.*

DISCUSSION

Analysis of hormonal evolution following bariatric surgery highlights a rapid normalization of the HPA axis and a partial adjustment of the oxytocinergic system, in strict accordance with the results reported by numerous clinical studies and reference reviews.

Regarding cortisol, the increased preoperative levels in morbid obesity (86.6 ± 50.2 ng/mL) align with data from the international literature, where obese patients present, on average, morning values between 80 and 90 ng/mL (Cornejo-Pareja *et al*., 2019). The significant 66% reduction at three months postoperatively to 29.5 ± 22.4 ng/mL confirms the normalization trend described by (Cornejo-Pareja *et al*., 2019) where rapid weight loss restores HPA homeostasis by 30-70% in the first year after surgery.

The statistically significant inverse correlation between percentage weight loss and cortisol decrease (r = -0.68) reflects similar observations from a Japanese study of patients undergoing sleeve gastrectomy where higher preoperative cortisol levels were correlated with lower weight loss (Bando *et al*., 2023). The role of cortisol as a prognostic biomarker is also supported by analyses that identified significant relationship between pre-surgical cortisol levels and the risk of long-term weight regain (Casteràs *et al*., 2024). Thus, our data complement the vast literature by highlighting an early, pronounced decline correlated with clinical parameters, suggesting the need to integrate cortisol monitoring into postoperative protocols to optimize long-term outcomes.

Regarding oxytocin, the values recorded before surgery (553 ± 115 pg/mL) fall within the range described by variable studies on plasma oxytocin in obesity, where levels can be up to 50% higher than in normal weight conditions (Pataky *et al*., 2019). The approximately 13% decrease to 483 ± 120 pg/mL, although partial, is consistent with reports indicating a reduction in oxytocin in the first 6-12 months after bariatric surgery, mediated by decreased fat mass (Becetti *et al*., 2023). The inverse correlation between weight loss and oxytocin adjustment (r = -0.42) supports the hypothesis of compensatory mechanisms by which excess adipose tissue stimulates the release of oxytocin, a roe also emphasized by preclinical experiments that attest to the lipolytic effects of the hormone (Ding *et al*., 2019). Furthermore, the connection between oxytocin adjustment and improved postoperative quality of life has been highlighted in several studies, where partial normalization of this neuropeptide was associated with reduced anxiety symptoms and improved social support (Lawson, 2017).

Beyond the effects of bariatric surgery, both age and adiposity exert independent influences on cortisol and oxytocin dynamics. Multiple clinical investigations have demonstrated that advancing age is associated with higher basal cortisol secretion, even after adjusting for BMI, whereas the relationship between oxytocin and age appears more variable.

Philips *et al.* (2011) reported that in men aged 50-70 years, plasma cortisol concentrations rose with increasing age and fell with higher BMI, highlighting a dual influence of chronological and metabolic factors on HPA axis tone. A meta-analysis by Tenk *et al.* (2016) further confirmed that the peripheral cortisol levels actually decline with healthy aging but may remain elevated in the presence of obesity, suggesting that adiposity can counteract the age-related decrease in cortisol secretion.

In our own cohort, we observed a modest positive correlation between age and baseline cortisol ($r = 0.31$), and a more pronounced cortisol reduction after surgery in younger patients, findings that align with these earlier reports and underscore the complex interplay between age, BMI and stress hormone regulation. The preoperative increase in cortisol reflects a neuroendocrine response to chronic stress, similar to that observed in populations subjected to intense psychosocial stress, such as nursing students, where academic stress is a significant predictor of depressive symptoms (Iorga *et al*., 2017).

Regarding adiposity, cortisol exhibits a U-shaped relationship with BMI, with nadirs in the overweight-class I range and rising levels at both lower and higher extremes of BMI (Schorr *et al*., 2015). Our positive baseline correlation ($r = 0.51$) and strong inverse link between BMI reduction and cortisol decrease ($r = -0.65$) mirrors these observations, reinforcing the concept that excessive fat mass constitutes a persistent activator of the HPA axis. Similarly, a large Korean cohort demonstrated that higher cortisol excretion was associated with favorable metabolic profiles despite greater adiposity, illustrating that cortisol adaptations may also reflect compensatory metabolic responses rather than simple stress markers (Park *et al*., 2011).

Oxytocin's association with age is less consistently reported. Some studies suggest stable oxytocin across the adult lifespan while others note subtle declines post menopause (Kerem, Lawson, 2021). In our data, age bore no significant relationship to oxytocin levels either pre- or post-surgery, implying that obesity-related factors overshadow age effects for this neuropeptide in the 21-65-year range.

With respect to BMI, oxytocin correlates positively with adiposity indices. Variable Oxytocin Levels in Humans revealed significant correlations between oxytocin and weight, waist circumference and BMI ($R^2 = 0.15$-0.16), reflecting higher oxytocin in more obese individuals (Pataky *et al*., 2019). A smaller pilot in women corroborated a positive BMI-oxytocin association ($r \approx 0.45$) (Skinner *et al*., 2019). Our finding of a baseline correlation ($r = 0.46$) and an inverse relationship between BMI loss and oxytocin reduction ($r = -0.39$) fits within this framework, suggesting that as fat mass decreases the compensatory elevation of oxytocin likewise diminishes.

Postoperative biomarker monitoring (e.g., cortisol, oxytocin) should be complemented with periodic psychological assessment, similar to recommendations for

nursing students, where screening is essential for early interventions and approaches that help patients' quality of life (Iorga *et al*., 2017).

CONCLUSIONS

In this study, it was highlighted that bariatric surgery causes significant changes in the hormone profile, especially in terms of cortisol and oxytocin, in the first three months postoperatively. These hormonal changes reflect complex physiological adaptations associated with weight loss and adiposity reduction.

Plasma cortisol levels decreased significantly, indicating a reduction in the activity of the HPA axis. This decrease in cortisol suggest an improvement in the stress response and a possible reduction in systemic inflammation associated with obesity.

Regarding oxytocin, a moderate decrease in plasma levels was observed postoperatively. This reduction may reflect an adaptation of the neuroendocrine system to the new post-surgical physiological conditions and a possible recalibration of appetite and eating behavior regulatory mechanisms.

The correlations identified between weight loss and hormonal changes suggest that body mass loss directly influences hormonal regulation. These findings highlight the importance of monitoring endocrine parameters in the postoperative period to better understand physiological adaptations and optimize intervention strategies.

In conclusion, the results obtained highlight the significant impact of bariatric surgery on hormonal regulation, highlighting the need for an integrated approach that includes endocrine monitoring in the postoperative management of severely obese patients.

IMPACT OF SIMULATED BRUSHING WITH DENTIFRICES ON ACRYLIC DENTURE BASE RESINS (Abstract): Aim of the study: The study aimed to evaluate the impact of simulated brushing with denture cleaning dentifrices on the surface roughness and weight loss of three types of PMMA denture base materials: heat-cured, CAD-CAM milled, and DLP printed. **Materials and Methods:** Ninety standardized samples were fabricated and subjected to brushing simulations using two commercial dentifrices (*Corega PurFrisch, Glaxo Smith Kline and Protefix Higiena, Queisser Pharma*) and distilled water as control. Surface roughness (Ra) and weight were measured at baseline, after 20,000 and 40,000 cycles, simulating up to four years of clinical use. **Results:** showed a progressive increase in surface roughness and a corresponding decrease in weight across all materials. Heat-cured PMMA exhibited the highest resistance to surface changes, with Ra values remaining below 0.4 µm and minor weight loss. DLP printed PMMA demonstrated the greatest susceptibility, with roughness values exceeding 0.56 µm and the most significant mass reduction. CAD-CAM milled samples showed intermediate behavior. The choice of dentifrice had minimal influence compared to the manufacturing method and mechanical action of brushing. **Conclusions:** The findings highlight the role of material processing techniques in determining long-term durability and suggest that brushing remains the primary factor in surface degradation. Clinicians should consider these differences when recommending cleaning methods and selecting denture materials. **Keywords:** POLYMETHYL METHACRYLATE RESIN, DENTURE HYGIENE, DENTURE CLEANING DENTIFRICE, SURFACE ROUGHNESS, WEIGHT LOSS.

INTRODUCTION

Partial or complete edentulism significantly affects aesthetics, speech, chewing, diet and quality of life. Dental prostheses are the standard treatment, with polymethyl methacrylate (PMMA) being the most commonly used denture base resin for over 70 years due to its aesthetics, strength, affordability, and biocompatibility (1-7). Heat-cured PMMA remains widely used, but it has drawbacks such as leaching of residual monomers, which may cause hypersensitivity and compromise material stability through water sorption and shrink-

age (6, 8). These issues have led to the development of improved materials and techniques.

Modern approaches like CAD/CAM and injection molding have enhanced denture fabrication. CAD/CAM dentures, made from pre-polymerized resins, offer better fit, reduced porosity, improved hygiene, good mechanical properties and color stability (9-14). However, challenges include difficulties in recording occlusal relationships, higher material and laboratory costs, and the absence of a trial denture stage (15-17).

Maintaining proper hygiene of PMMA-based dentures is essential for oral health and the long-term performance of the prosthesis. Mechanical cleaning methods, such as manual brushing, ultrasonic baths, and the use of effervescent denture cleansers, are widely recommended due to their effectiveness in reducing plaque and biofilm (18, 19). Additionally, common household agents such as bleach and vinegar offer practical and accessible alternatives for denture cleaning (20, 21). For individuals with limited manual dexterity, particularly elderly patients, denture cleaning dentifrices and antiseptic soaps, present a convenient and effective solution (22-24). However, long-term use of these agents may compromise the material's properties, leading to surface roughness, increased monomer release, and reduced flexural strength.

The aim of this study was to evaluate the effect of brushing with denture cleaning dentifrices on the surface properties of PMMA denture base material. The null hypothesis of the study stated that brushing PMMA denture base material with two different dentifrices does not produce a statistically significant change in surface roughness or weight loss, under simulated conditions equivalent to two years of use in a healthy individual.

MATERIALS AND METHODS

The experimental study was conducted at the Faculty of Dental Medicine, Grigore T. Popa University of Medicine and Pharmacy Iași, in partnership with the Faculty of Materials Science and Engineering, Gheorghe Asachi Technical University of Iași.

A total of 90 resin samples were fabricated using materials suitable for conventional, CAD-CAM subtractive, and additive denture manufacturing (fig. 1).

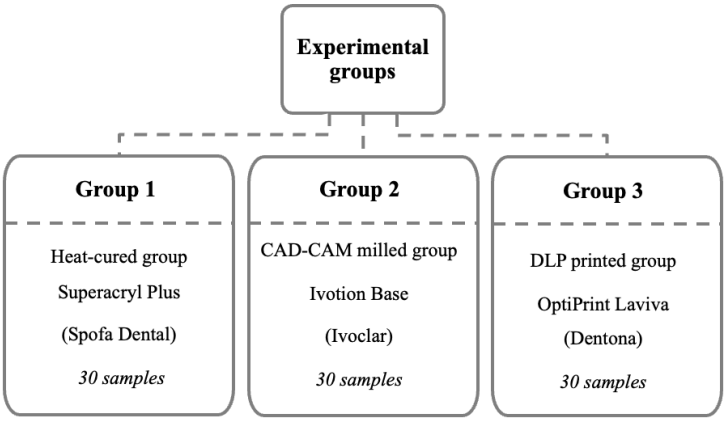

Fig. 1. Experimental groups

The samples were tested using a soft bristle brush (Tribest), and two commercially available denture cleaning dentifrices, Corega PurFrisch (GlaxoSmithKline), Protefix Higiena (Queisser Pharma).

The sample design was created using Autodesk MeshMixer (Autodesk Inc., USA) and featured dimensions of 65 mm in length, 10 mm in width, and 2 mm in thickness (fig. 2).

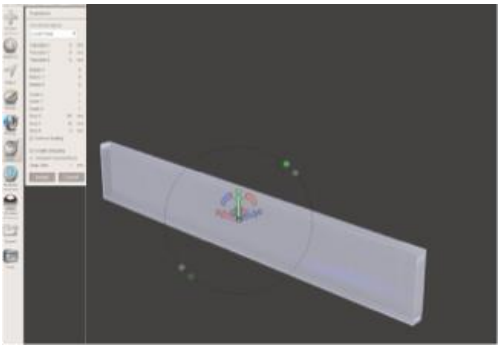

Fig. 2. Digital design of the PMMA samples created in Autodesk MeshMixer

Heat-cured samples were fabricated using Superacryl Plus resin (Spofa Dental), following the manufacturer's guidelines. For the subtractive manufacturing group, a 5-axis dental milling machine (VHF K5 Plus, VHF, Germany) was employed to mill the experimental samples from CAD/CAM denture base resin discs (Ivotion Base, Ivoclar). For the additive manufacturing method the STL files were transferred to a digital light processing (DLP) printer (Asiga MAX, ASIGA, Australia) and printed using OptiPrint Laviva resin (Dentona).

All samples were finished and polished using 1000-grit abrasive paper under continuous water cooling to obtain a smooth, mirror-like surface. After polishing, the samples were immersed in distilled water and maintained at 37 °C for 24 hours.

The brushing simulation in this study was conducted using the ZM-3 Toothbrush Simulator (SD-Mechatronik), which is equipped with three heads designed to accommodate toothbrushes. Three samples were tested simultaneously. The toothbrushes were secured in the simulator using screws located on the sides and top of each head. These screws were adjusted to ensure accurate alignment and leveling of each toothbrush during the simulation.

The brushing simulator was programmed to operate at a frequency of 75 strokes per minute, with each stroke covering a distance of 3.8 cm and applying a vertical load of 0.2 N (200-g vertical load). The testing device provided horizontal and vertical movements. The brushing test was carried out for 20,000 and 40,000 cycles, simulating up to two to four years of prosthesis use under conditions representative of a healthy person.

For each sample, three roughness measurements were recorded after the finishing and polishing process using a contact-type roughness tester, Form Talysurf® (Taylor Hobson, Leicester, England). The arithmetic mean roughness parameter (R_a) was used.

After the brushing procedure, the samples were carefully removed from the simulator and subjected to ultrasonic cleaning with pure water for 10 min twice before the measurements, and their surfaces were dried with warm air.

Each sample was subsequently weighed using an analytical balance with an accuracy of 0.1 mg (Adam, Adam Equipment, UK) in order to determine the material weight.

Data analysis was carried out using IBM *SPSS Statistics* software (version

26.0; IBM Corp., Armonk, NY, USA). Comparisons between groups were made using the Kruskal-Wallis test, with statistical significance determined at a threshold of $p < 0.05$.

RESULTS

Across all materials, surface roughness increased with the number of brushing cycles, confirming that prolonged mechanical action impacts denture base surfaces. However, the extent of this increase was clearly material-dependent. Heat-cured PMMA showed the highest surface stability, with surface roughness rising only slightly from a baseline of 0.366 ± 0.069 µm (distilled water) to 0.398 ± 0.067 µm after 40,000 brushing cycles. Similarly small changes were observed with Corega PurFrisch (from 0.371 ± 0.065 µm to 0.378 ± 0.066 µm) and Protefix Higiena (from 0.369 ± 0.073 µm to 0.376 ± 0.072 µm), suggesting excellent resistance to wear over time. In contrast, DLP printed PMMA exhibited the greatest surface changes, with roughness values increasing substantially across all conditions. The Protefix subgroup showed the highest increase, from 0.495 ± 0.066 µm at baseline to 0.565 ± 0.063 µm at 40,000 cycles—a change of +0.070 µm. Even in distilled water, the DLP group experienced an increase from 0.494 ± 0.067 µm to 0.561 ± 0.063 µm, further emphasizing the material's susceptibility to surface degradation. CAD-CAM milled PMMA demonstrated intermediate behavior. The surface roughness increased from 0.455 ± 0.109 µm (distilled water) to 0.488 ± 0.104 µm, and from 0.462 ± 0.096 µm to 0.470 ± 0.092 µm in the Corega group. While this group was more stable than the DLP-printed samples, it was still more affected than the heat-cured group (tab. I).

Independent-Samples Kruskal-Wallis Test; significant level $p < 0.05$

Over the course of the simulated brushing cycles, all PMMA denture base materials showed a gradual decrease in weight, indicating material loss as a result of mechanical wear. However, the extent of this weight loss varied depending on the type of material and, to a smaller degree, the cleansing agent used. The heat-cured PMMA group started with the highest initial weight, averaging around 8.69 mg across all subgroups. After 40,000 brushing cycles, the samples immersed in distilled water dropped to 8.49 ± 0.276 mg, while those treated with Corega and Protefix fell to 8.395 ± 0.261 mg and 8.359 ± 0.2938 mg, respectively. In comparison, the CAD-CAM milled PMMA group began with a slightly lower initial weight of approximately 8.46 mg. While the weight loss was still moderate, it was more noticeable than in the heat-cured samples. After 40,000 cycles, samples treated with distilled water weighed 8.311 ± 0.038 mg, and those brushed with Corega or Protefix ended at 8.231 ± 0.039 mg and 8.210 ± 0.037 mg, respectively. The most substantial changes were observed in the DLP printed PMMA group. These samples began with the lowest baseline weight (around 8.355 mg) and showed the greatest material loss after brushing. By the end of the 40,000 cycles, weights had decreased to 8.176 ± 0.072 mg in distilled water, 8.125 ± 0.067 mg with Corega, and 8.105 ± 0.064 mg with Protefix (tab. II).

TABLE II.

Weight of PMMA study groups immersed in different cleansing agents before and after 20,000 and 40,000 brushing cycle

Study groups	Cleansing agents immersion	Weight (mg) Mean ± Std. Deviation

DISCUSSION

Maintaining a smooth and clean denture surface is essential for minimizing microbial colonization and biofilm formation, particularly from organisms like *Candida albicans*, which is associated with inflammation, halitosis, and systemic infections (4,25). Denture surfaces can become contaminated during fabrication and clinical use, increasing the risk of cross-infection between patients and clinicians (26-29).

For surface roughness (Ra), the null hypothesis was retained across all material groups-heat-cured, CAD-CAM milled, and DLP printed PMMA-regardless of the cleansing agent used (Corega PurFrisch, Protefix Higiena, or distilled water). Although the type of cleansing agent did influence surface roughness to some extent, its impact was less significant than the manufacturing method or the number of brushing cycles. In most cases, Corega and Protefix produced smaller increases in roughness compared to brushing in distilled water, suggesting that properly formulated denture cleansers may offer a slight protective effect against surface wear. These findings agree with Paranhos *et al*. (30), who emphasized that mechanical action plays a more critical role than cleanser composition in influencing surface degradation of denture materials.

While a slight increase in surface roughness was observed after 20,000 and 40,000 brushing cycles, this effect was consistent across all cleansing agents and within the expected threshold of clinical tolerance. Even after extended brushing, surface roughness values remained below 0.6 µm, which is near the threshold for microbial adhesion but still within clinically acceptable limits (31,32).

Regarding weight loss, the null hypothesis was retained for the heat-cured PMMA group at all time points ($p > 0.05$), indicating no significant influence of the denti-

frice type on material mass loss. However, for CAD-CAM milled and DLP printed PMMA, the null hypothesis was rejected after 20,000 and 40,000 brushing cycles, with p-values < 0.05. This implies that the type of cleansing agent had a statistically significant effect on weight loss in these two material groups, especially after prolonged mechanical wear. The findings align with and expand upon existing literature, emphasizing that both the manufacturing method and the mechanical stresses induced by brushing play pivotal roles in determining material performance. Alfouzan *et al*. (33) conducted a detailed investigation into the effects of brushing and thermal aging on 3D-printed resins, reporting significant increases in surface roughness confirmed through profilometry and scanning electron microscopy (SEM). Similarly, Chang *et al*. (34) reported that while brushing increased roughness and weight loss in both conventional and printed denture base materials, the milled resins showed greater mechanical stability, with material hardness identified as a key factor in abrasion resistance.

The observed differences in material performance can largely be attributed to variations in material composition and polymerization processes. Heat-cured PMMA, which undergoes conventional thermal polymerization, demonstrated the highest stability and resistance to degradation. CAD-CAM milled resins, although pre-polymerized, may be more prone to surface loss due to their relatively brittle structure. DLP printed resins, fabricated using photo-initiated polymerization, typically exhibit lower crosslink density and higher water sorption, making them more vulnerable to wear (6).

In general, mechanical brushing remains an effective method for maintaining denture hygiene; however, it also contributes to the gradual wear of PMMA materials. Over time, the combination of mechanical action and abrasive components in dentifrices—such as silica or calcium carbonate—can lead to deterioration in surface polish and a measurable reduction in denture mass (6). Moreover, surface abrasion is influenced by multiple variables: the abrasiveness of the dentifrice, brush stiffness, brushing force, technique, frequency, and the denture material's mechanical properties (32, 35).

Despite the contributions of this study, several limitations must be noted. First, the in vitro design, while enabling control and reproducibility, does not replicate the complex conditions of the oral cavity, such as temperature changes, salivary enzymes, pH fluctuations, and microbial activity. Secondly, only two denture cleaning dentifrices (Corega PurFrisch and Protefix Higiena) were tested, limiting the applicability of results across the wide range of products available. The brushing brushing parameters were standardized, though in real-life conditions, patient habits vary greatly in technique, force, and frequency, potentially affecting material wear outcomes. Moreover, the study focused solely on surface roughness and weight loss. Important properties such as color stability, hardness, and microbial adhesion were not evaluated.

Future studies should aim to incorporate in vivo elements or simulate the oral environment more realistically through artificial saliva, thermocycling, and microbial challenges. Additionally, expanding the range of dentifrices, incorporating more

diverse material types, and examining biofilm accumulation and patient-centered outcomes would enhance the clinical relevance of the findings.

CONCLUSIONS

The findings of this study demonstrate that brushing with denture cleaning dentifrices leads to a progressive yet controlled increase in surface roughness and a gradual loss of material weight across all PMMA denture base materials tested. Importantly, the differences observed between cleansing agents were minimal, indicating that brushing itself, rather than the chemical composition of the dentifrices, was the primary factor influencing surface degradation.

Among the three types of PMMA materials evaluated, DLP-printed PMMA was the most susceptible to surface wear and weight loss, while heat-cured and CAD-CAM milled PMMA exhibited superior resistance to these changes under identical experimental conditions. This highlights the manufacturing method as a key determinant of the material's mechanical durability and overall performance.

At all-time points, the choice of denture cleanser did not significantly impact surface roughness or weight within each material group, further emphasizing that the mechanical action of brushing was the dominant contributor to wear. Clinically, this suggests that all tested cleansing agents are similarly effective in preserving surface integrity, particularly for heat-cured PMMA.

These results underscore the importance of selecting appropriate materials for denture fabrication and educating patients on gentle but effective cleaning techniques. While regular brushing is essential for maintaining oral hygiene, it can accelerate wear in less durable materials. Therefore, proper hygiene practices combined with the selection of more wear-resistant materials can help reduce microbial colonization, minimize the risk of denture-related infections, and ultimately extend the functional lifespan of prosthetic devices.

THE ASSESSMENT OF THE PROTECTIVE EFFECT OF THEOBROMINE, CAFFEINE AND THEOPHYLLINE ON INDUCED-OXIDATIVE STRESS IN ZEBRAFISH INTESTINE

THE ASSESSMENT OF THE PROTECTIVE EFFECT OF THEOBROMINE, CAFFEINE AND THEOPHYLLINE ON INDUCED-OXIDATIVE STRESS IN ZEBRAFISH INTESTINE (Abstract): Oxidative stress, through the disbalance between oxidant and antioxidant mechanisms, plays an important role in intestinal disorders and dysfunctions. Evidence reported that methylxanthines possess antioxidant and anti-inflammatory properties, but their role in reducing oxidative stress-induced intestinal damage remains poorly understood. **Aim**: In this study, adult zebrafish (*Danio rerio)* were exposed to zinc oxide nanoparticles (ZnO-NPs) to induce oxidative intestinal injury and to evaluate the potential protective effects of methylxanthines (caffeine, theophylline, and theobromine). **Materials and methods:** Adult zebrafish were randomly divided into eight groups: control, oxidative stress-induced (treated with ZnO nanoparticles), oxidative stress and theobromine, oxidative stress and caffeine, oxidative stress and theophylline, theobromine treated group, caffeine treated group, theophylline treated group. After 15 days of exposure, intestinal samples were processed for histopathological evaluation; microscopic images were analyzed for villus, epithelial integrity and goblet cells density. Representative biochemical markers of antioxidant defense-superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx1), and reduced glutathione (GSH) were quantified to assess redox status. **Results:** Histological examination revealed that ZnO-NPs induced intestinal damage, including epithelial disruption, blunt villus shortening and a discrete increase in the number of goblet cells, which were attenuated in oxidative stress methylxanthine-treated groups. The biochemical data supported these findings, showing enhanced antioxidant enzyme activities and restored GSH levels in protected groups. Correlation analysis demonstrated associations between enzymatic antioxidant capacity and histopathological integrity. **Conclusions:** Methylxanthines can differentially modulate the intestinal oxidative stress, providing a basis for future studies on their potential therapeutic or dietary application. Theobromine appears to confer greater preservation of intestinal structure and mucosal balance. **Keywords:** OXIDATIVE STRESS, INTESTINE**,** THEOBROMINE, CAFFEINE, THEOPHYLLINE, ZEBRAFISH.

INTRODUCTION

Evidence shows that due to their high prevalence and impact, gastrointestinal diseases represent a consistent problem for modern medicine. The oxidative stress, generating a high level of reactive oxygen species (ROS), which cannot be countered by antioxidant mechanisms, is deeply in-

volved in the pathogenesis of a large number of intestinal diseases, including colorectal cancers, inflammatory bowel disease, diverse metabolic disorders and enteric infections (1, 2). To date, current therapies to these conditions remain ineffective in restoring normal intestinal integrity and physiological functions. Understanding the correlation between oxidative stress and antioxidant defense mechanisms requires a complex process, based on the selection of an appropriate biological model, a distinct target tissue, and specific bioactive compounds (3). Based on this reasoning, our study was designed to explore how and if methylxanthines influence oxidative balance in zebrafish intestinal tissue, reflected in the histopathological analysis of intestinal morphology (4). The motivation for our investigation started from the limited existing research about the potential of methylxanthines to modulate intestinal oxidative stress. Our previous biochemical investigation demonstrated that ZnO-NP exposure in adult zebrafish disrupts antioxidant defenses and elevates oxidative stress markers, while methylxanthines such as theobromine, caffeine, and theophylline exhibit notable antioxidant activity. Building on these findings, the present study evaluates the histopathological changes in zebrafish intestine following ZnO-NP exposure and assesses the protective effects of these methylxanthines. In this context, we intended to find an answer for three main questions related to oxidative stress: why focus on intestine, why use zebrafish and why investigate methylxanthines (5). This approach integrates three key perspectives already mentioned: the intestine as a primary site of absorption for most bioactive compounds and presenting oxidative vulnerability, the zebrafish as an extremely relevant model for redox biology, and methylxanthines as widely consumed bioactive molecules with both beneficial and adverse gastrointestinal effects (6). Together, these elements provide complex information to assess the potential protective role of methylxanthines against intestinal oxidative stress.

MATERIAL AND METHODS

Study design. The experimental design and exposure protocol were identical to those used in a companion study focusing on biochemical antioxidant parameters, submitted separately for publication. In brief, adult zebrafish (*Danio rerio)* (6 months old, both sexes) were acclimated for two weeks before being randomly distributed into eight groups (n = 15 per group, in triplicate): Experimental groups were exposed for 15 days to zinc oxide nanoparticles (ZnO-NPs; 0.69 mg/L) alone or in combination with methylxanthines (caffeine, theophylline, or theobromine; 50 mg/L each). Additional groups received methylxanthines only under the same conditions.

Histological processing. At the end of the exposure period, zebrafish were euthanized by gradual cooling in ice-chilled water, following AVMA guidelines (2020). Intestinal samples were fixed in 10% neutral buffered formalin for 24 h, dehydrated, cleared in xylene and embedded in paraffin. Sections (5 μm) were stained with hematoxylin and eosin (H&E) for morphological examination. The slides were examined using a light microscope (Zeiss Axiolab 5), and representative images were captured with a digital camera system (Axiocam 208 color camera). Histopathological evaluation included qualitative assessment of structural alterations including epithelial degeneration, adipocyte distribution, and villus disorganization, and quantitative,

based on goblet cells count.

Biochemical Data. The activities of SOD, CAT, and GPx1, along with reduced GSH levels, were performed as part of the companion biochemical study submitted separately. The resulting data were used here to establish correlations with intestinal histopathological changes.

Statistical Analysis. Data were collected and subjected to analysis using statistical analysis as Spearman's rank correlation, Principal Component Analysis (PCA) and multiple linear regressions. The normality of distributions within the groups was verified for each variable across groups using the Shapiro-Wilk test ($p > 0.05$ for all parameters).

Ethics. The study design and protocol were approved by the Ethics Committee of Grigore T. Popa University of Medicine and Pharmacy Iasi, Romania (No. 325/15.06.2023).

RESULTS

The intestinal morphology of zebrafish from the control (fig. 1A), theobromine (fig. 1F), caffeine (fig. 1G), and theophylline groups (fig. 1H) presented a normal morphology, with a mucosal lining presenting well-organized villi and intact epithelial linings, in which goblet cells are normally distributed, indicating that the tested methylxanthine doses did not exert any structural alterations. In contrast, the histological evaluation of zebrafish intestines revealed that oxidative stress induced marked structural alterations, including epithelial degeneration, villi appeared blunt, fused or eroded, without the normal regular disposal, lamina propria is enlarged, with inflammatory cell infiltration, and there is a relatively moderate increase number of goblet cells, consistent with their hyperplasia and hypertrophy (fig. 1B).

These lesions are characteristic of oxidative damage in intestinal tissues, where excessive production of ROS compromises mucosal defense, fact that will affect mucosal morphology, disrupting the intestinal barrier.

Among the oxidative stress-treated groups, co-treatment with theobromine resulted in substantially milder histopathological alterations; (fig. 1C). Although, the villi remain irregularly distributed, the intestinal epithelium in the OS + theobromine group exhibited improved structural preservation and a more balanced goblet cell morphology, compared with the OS + caffeine (fig. 1D) and OS + theophylline groups (fig. 1E).

ZnO-NP exposure induced oxidative stress, reflected by increased GPX1, SOD and CAT levels with concurrent GSH depletion, this biochemical imbalance being followed by a moderate rise in goblet cell number, suggesting an acute mucosal defense reaction (tab. I).

However, Spearman correlation analysis (fig. 2) revealed no significant associations between the number of intestinal goblet cells and the biochemical oxidative stress markers (GPX1, CAT, SOD, and GSH).

Although weak positive trends were observed with and CAT ($r_s = 0.57$), these did not reach statistical significance ($p > 0.05$), indicating that the epithelial response was not directly coupled with the magnitude of enzymatic antioxidant modulation.

Principal Component Analysis (PCA) was applied to the normalized group means to explore covariation patterns among oxidative stress biomarkers and the histological parameter (number of goblet cells). The first two components (F1 and F2) explained 72.18% of the total variance (42.84% and 29.33%, respectively), indicating a good model fit for biological interpretation (fig. 3).

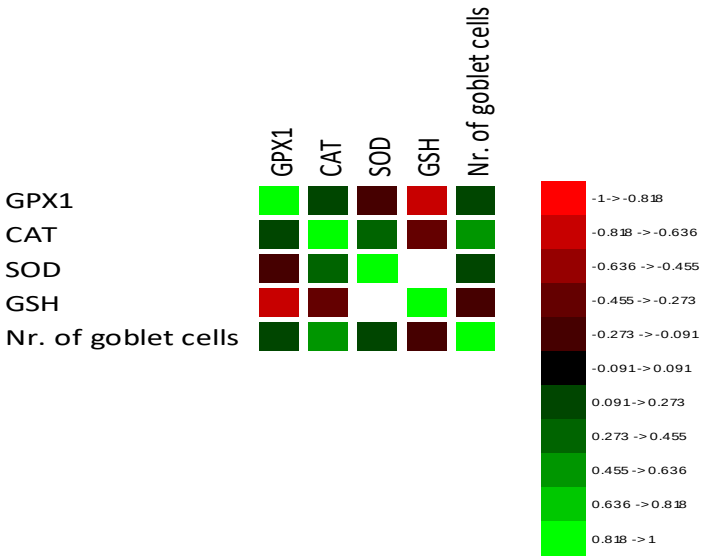

Fig. 2. Correlation matrix.

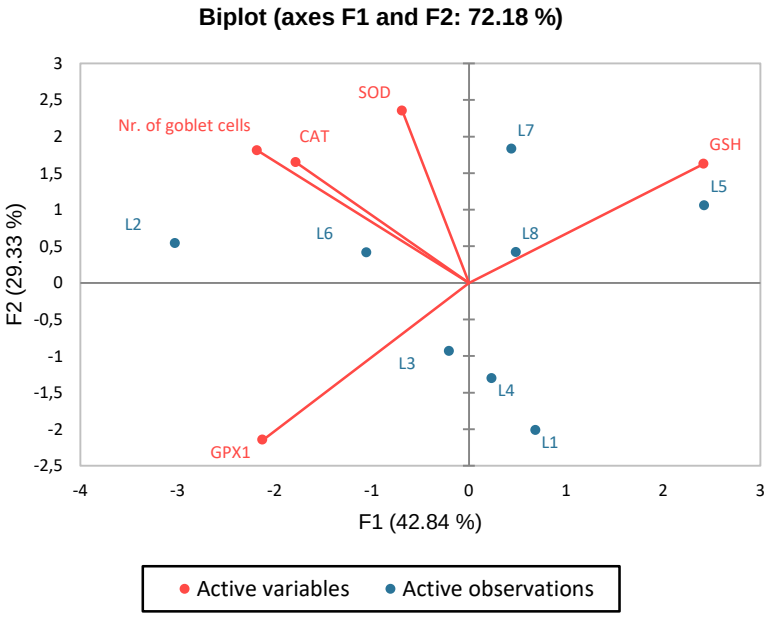

Fig. 3. PCA analysis for biochemical parameters and number of goblet cells

Axis F1 primarily opposed GPX1 (negative projection) to GSH (positive projection), describing a redox gradient between intense oxidative stress characterized by peroxidase hyperactivity and depleted glutathione, and a restored redox state defined by elevated GSH and reduced GPX1 activity. Axis F2 was defined mainly by positive loadings of CAT, SOD, and the number of goblet cells, indicating an adaptive enzymatic response associated with epithelial protection. Among experimental groups, the ZnO-NPs group was positioned in the negative region of F1, close to GPX1, confirming a strong oxidative stress profile with limited epithelial adaptation. The co-exposure groups occupied an intermediate position, due to a partial restoration of redox balance under the influence of methylxanthines. Notably, ZnO-NPs + theobromine group was projected near GSH and goblet cells, consistent with improved antioxidant status and epithelial recovery.

The methylxanthine-only groups were located in the upper-right quadrant, close to CAT, SOD, and goblet cells, reflecting a moderate enzymatic activation and maintenance of GSH levels, typical of adaptive, non-stressful antioxidant stimulation.

PCA revealed that the number of intestinal goblet cells clustered with the antioxidant enzymes CAT and SOD, indicating a coordinated adaptive response involving both enzymatic defense and epithelial protection. Conversely, the number of goblet cells were positioned opposite to GPX1, reflecting the harmful impact of severe oxidative stress on mucosal integrity. Their proximity to GSH show that restoration of intracellular thiol balance parallels epithelial regeneration. Thus, methylxanthine exposure, particularly with theobromine, shifted the epithelial profile toward a protective and secretory phenotype, mitigating

the histopathological effects of ZnO-NPs.

A multiple linear regression model was constructed using the number of intestinal goblet cells as the dependent variable and GPX1, CAT, SOD, and GSH as explanatory variables. The model showed a high coefficient of determination (R^2 = 0.872; adjusted R^2 = 0.701), indicating that approximately 70% of the variability in goblet cell number could be explained by the biochemical parameters. The residuals followed a normal distribution (Shapiro-Wilk p = 0.783), confirming the validity of the model assumptions (fig. 4).

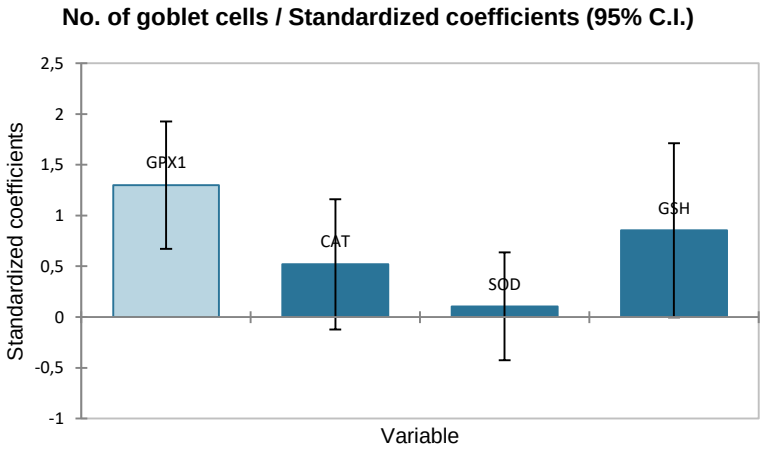

Fig. 4. Multiple linear regression model showing standardized coefficients (β ± 95% CI) for oxidative stress biomarkers (GPX1, CAT, SOD, GSH) as predictors of intestinal goblet cell number in zebrafish.

The standardized coefficients revealed differentiated contributions of oxidative markers to epithelial alterations. GPX1 (β=1.299, p=0.007) and GSH (β=0.854, p=0.051) showed positive associations with goblet cell number, whereas CAT and SOD displayed weaker, non-significant effects (p>0.05). Among the oxidative biomarkers included in the model, GPX1 emerged as the strongest predictor of goblet cell number, followed by GSH. These findings are consistent with PCA, which positioned goblet cells near CAT/SOD and apart from GPX1, indicating that mucosal hypersecretion occurs both as an irritative response under strong oxidative load and as an adaptive response when redox balance is restored.

DISCUSSION

The particular susceptibility of the intestine to oxidative stress presents major challenges, as it contributes to the development of numerous complex diseases with poorly and only partially understood mechanisms, limiting the effectiveness of current therapeutic approaches. Prolonged exposure to oxidative stress has been linked to alterations of intestinal mucosa, affecting the heterogenous cell population of intestine, by directly damaging the enterocytes and the goblet cells, changes that

are often reflected by a reduction in villus height and loss of epithelial integrity (1).

Zebrafish models are increasingly used to decipher the implications of oxidative stress in intestine, providing an advantage over other experimental models, by facilitating an efficient translation of results in humans (7). Because zebrafish oxidative qualitative mechanisms - such as ROS production, lipid peroxidation or apoptotic signaling - are largely comparable with those in humans, zebrafish models represent a potential translational system, generating reproducible data that enhance our understanding of oxidative stress mechanisms, with potential implications for human health and therapeutic development.

Exposure to ZnO Nps triggers a sequence of mechanisms that interact and influence the morphology of the intestine. The excess ROS, through a specific oxidative induction, subjects enterocytes to a specific apoptotic process, which can be able to generate changes in villus length and morphology (8). On the one hand, ZnO will promote inflammation and the presence of activated immune cells will increase tissue injury. On the other hand, studies reported another major impediment in restoring the integrity of intestinal barrier, namely a strong inhibition of intestinal stem cells proliferation, who will no longer be able to replace the nonfunctional epithelial cells (9). Each time it should be noted that these effects are strongly dependent on dose, exposure route and exposure time.

Methylxanthines, a class of naturally occurring alkaloids that include caffeine, theobromine, and theophylline, are widely consumed through beverages and foods such as coffee, tea, and cocoa (10). These compounds exhibit various bioactive properties, including antioxidant, anti-inflammatory, and neuroprotective effects (11). While numerous studies have explored the impact of methylxanthines on oxidative stress in respiratory or nervous or cardiovascular systems (12), limited data exist regarding their influence on intestinal oxidative damage in zebrafish (*Danio rerio*), a rapidly emerging experimental model in gastrointestinal research.

One may question why research on methylxanthines has not advanced further in the field of gastrointestinal pathology. In this context, we have to consider that their primary molecular targets are more functionally relevant to the nervous and respiratory systems, (where they are already extensively applied), whereas their gastrointestinal effects are broad, nonspecific, and difficult to interpret or translate into therapeutic applications (13).

Although methylxanthines have traditionally been explored for their effects on the nervous and respiratory systems, we consider that their potential relevance to intestinal oxidative stress deserves renewed attention. With both direct and indirect antioxidant properties, acting as free radical scavengers while also modulating endogenous defense mechanisms such as SOD, CAT, and GPx activity. In addition, methylxanthines influence adenosine receptor signaling, a key pathway in the regulation of intestinal inflammation and oxidative injury, particularly under hypoxic or ischemic conditions (14).

Their phosphodiesterase-inhibiting activity has a significant role to maintain epithelial protection by maintaining intracellular cAMP levels, stimulating barrier integrity, and decreasing ROS generation. Because they have well-established pharmacological profiles, accessibility, and systemic antioxidant effects, methylxan-

thines may be regarded as promising but insufficiently investigated agents against oxidative stress-mediated intestinal injury. Further research is needed to define their molecular interactions in the intestinal microenvironment and to explore their possible role as adjuvant therapies, in oxidative or inflammatory gastrointestinal disorders. (15)

The histological evaluation of zebrafish intestine in our study revealed that oxidative stress induced specific structural alterations, including epithelial degeneration, villus shortening, and inflammatory cell infiltration (16, 17). These lesions are characteristic of oxidative damage in intestinal tissues, where excessive production of reactive oxygen species (ROS) disrupts epithelial integrity and compromises mucosal defense. In contrast, the intestinal morphology of zebrafish from the control, theobromine, caffeine, and theophylline groups remained normal, with well-organized villi and intact epithelial linings, indicating that the tested methylxanthine doses did not exert injuries of the intestinal wall, which is very important in determining their precise role under normal conditions (18).

When ZnO-NPs are added to tank water, zebrafish constantly ingest water, so the intestinal mucosa receives a direct dose of ZnO-NPs, which accumulate in the intestine. Although some studies report a decrease in goblet cell density following ZnO-NP exposure, our findings revealed a relatively discrete increase after 15 days of treatment. We consider that this fact suggests a compensatory mechanism that enables the intestinal mucosa to adapt the oxidative stress resulting from NPs accumulation. Goblet cell differentiation, with mucus hypersecretion could be considered as transient response to ZnO-Np induced alterations, which helps preserve the integrity of intestinal barrier, supported by the protective mucus coating (18, 19). With higher doses or prolonged exposures, depletion of secretory cells become evident, impairing intestinal epithelium integrity and is followed by the goblet cell loss, as in severe chronic exposure, reported in other studies (20, 21).

Co-treatment with theobromine attenuated these histological changes, resulting in improved epithelial preservation and a more balanced goblet cell distribution compared with the oxidative stress + caffeine and oxidative stress + theophylline groups. These findings suggest that theobromine provides a stronger protective influence against oxidative stress-induced mucosal injury, possibly through its antioxidant and anti-inflammatory actions, including ROS scavenging and effect on cell membranes (22).

The statistical analyses provided additional insight into the relationship between oxidative stress biomarkers and intestinal epithelial alterations. Although ZnO-NP exposure produced a pronounced biochemical imbalance - characterized by elevated GPX1, CAT, and SOD levels with concurrent GSH depletion - Spearman's rank correlation revealed no significant linear associations between oxidative stress markers and goblet cell counts. The weak positive trend observed with CAT (r_s = 0.57, $p > 0.05$) indicates that epithelial secretory adaptation may not be directly proportional to enzymatic modulation but rather reflects a complex, nonlinear tissue response to oxidative injury.

Principal Component Analysis (PCA) provided additional insight, explaining 72.18% of the total variance and distinguishing clear redox and epithelial patterns.

The first component (F1) opposed GPX1 and GSH, describing a transition from oxidative overload toward restored redox balance. The second component (F2), defined mainly by CAT, SOD, and goblet cells, indicated an adaptive enzymatic-epithelial response. The ZnO-NP group clustered with GPX1, confirming a strong oxidative profile, while theobromine co-treatment was projected near GSH and goblet cells, reflecting partial restoration of thiol balance and epithelial recovery. Also is consistent with histological observations of reduced epithelial damage. The methylxanthine-only groups were associated with moderate antioxidant activation and preserved mucosal integrity.

The multiple linear regression model confirmed these multivariate patterns, showing that oxidative biomarkers collectively explained approximately 70% of the variability in goblet cell number (R^2 = 0.872; adjusted R^2 = 0.701). GPX1 emerged as the strongest independent predictor (β = 1.299, p = 0.007), followed by GSH (β = 0.854, p = 0.051), while CAT and SOD displayed weaker, non-significant effects. These relationships indicate that the goblet cell hyperplasia may occur as a result of two factors: an irritative reaction under intense oxidative condition and as an adaptive process, accompanying the restoration of redox homeostasis (23). Together, these multivariate analyses support the hypothesis that theobromine modulates oxidative-epithelial interactions more efficiently than caffeine or theophylline, promoting epithelial recovery through a balanced antioxidant response.

CONCLUSIONS

Collectively, the histological and statistical data demonstrate that although all three methylxanthines share a similar chemical structure, their biological effects under oxidative stress are different. Theobromine exhibits the most effective modulation of oxidative-epithelial interactions, promoting intestinal protection through balanced antioxidant responses and maintenance of epithelial integrity. When interpreted alongside the biochemical data (SOD, CAT, and GPx), these histological findings support the potential of theobromine as a milder, but biologically active methylxanthine, providing a better protection against oxidative damages, compared with caffeine and theophylline, with significant implications for managing oxidative stress-related intestinal injuries.

CONFLICT OF INTEREST AND FUNDING

MOTIVATION AND DECISION-MAKING FACTORS IN CHOOSING BARIATRIC SURGERY. A PROSPECTIVE STUDY (Abstract): Understanding patients' reasons for undergoing bariatric surgery and their expectations regarding their next surgery it is important to provide best clinical practice and reduce unrealistic expectations. **Materials and methods**: The present study represents a prospective cohort, which included 65 patients undergoing bariatric surgery at the Iași Bariatric Surgery Center, Romania, between April 2023 and April 2024. The preoperative evaluation included the analysis of the reasons why the patients opted for surgery, as well as the collection of anthropometric, socio-professional data and associated comorbidities. The postoperative evaluation aimed at weight loss and the evolution of the results obtained following the surgery. **Results**: The mean change in body mass index (BMI) before and after surgery was 14.42 kg/m². At 1 year after surgery, the mean percentage of excess weight loss (%EWL) was 66.04%. Before surgery, the most frequently reported reason for requesting surgery was weight loss (47.9%), and this was maintained postoperatively, followed by improved self-esteem and reduced comorbidities. **Conclusions:** The main reason for seeking bariatric surgery was weight loss. However, despite significant weight loss, self-esteem was the element that generated the greatest satisfaction after surgery. Our findings may be useful in the clinical context, when patients are informed before surgery about what to expect, as well as when meeting with a patient after surgery to discuss aftercare. **Keywords:** OBESITY, BARIATRIC SURGERY, EXPECTATION, WEIGHT LOSS.

INTRODUCTION

Obesity has become one of the greatest global public health challenges of the 21st century. Obesity has reached epidemic proportions worldwide, with over 1 billion people classified as obese in 2022, representing 13% of the global population (1,2,3).

Bariatric surgery is currently considered the most effective long-term treatment for morbid obesity when lifestyle interventions fail to achieve healthy and sustained weight loss (4).

Bariatric surgery is divided into two classes: restrictive procedures (e.g., sleeve gastrectomy) and gastrointestinal bypass procedures (e.g., Roux-en-Y gastric bypass). Both restrictive and gastrointestinal bypass procedures produce significantly greater weight loss and more profound improvements in glucose tolerance than medical treatments (5).

Bariatric surgery improves morbidities such as diabetes and cardiovascular disease

and reduces the risk of developing cancer (6, 7).

It is associated with a low risk of complications and has been shown to be more effective than conservative treatment for long-term weight loss and control of type 2 diabetes (8).

Although bariatric surgery is typically associated with significant overall weight loss (e.g., 30%–50% of excess weight within the first 6 months and 71% of excess weight at 1 year after surgery), a reduction in medical and psychological comorbidities, and an improved quality of life. Insufficient weight loss (<50% excess weight loss) is also the most common reason for performing additional bariatric surgery (9).

Although bariatric surgery is recognized as a safe and successful treatment for obesity despite good results in terms of weight loss after surgery, patients are not always satisfied due to unrealistic expectations (10, 11).

Patients undergoing nonsurgical weight loss treatments have similar unrealistic expectations, but some studies indicate that high expectations lead to greater weight loss (12, 13).

Previous studies exploring patients' expectations of bariatric surgery have focused primarily on weight loss and, to some extent, on quality of life. Preoperative reasons for seeking bariatric surgery have been explored to some extent, but no prospective follow-up has been conducted after surgery (14, 15).

This study aims to explore the main reasons for seeking bariatric surgery and to further investigate which aspects patients report as most satisfying after surgery. In addition, we aimed to study patients' perceived satisfaction with the surgical outcome and the association with postoperative weight loss and quality of life. Our hypotheses are that, regardless of patient-related factors, weight loss remains the most important reason for seeking surgery, and the degree of satisfaction with the postoperative outcome depends on the amount of weight loss.

MATERIALS AND METHODS

We performed a prospective analysis of data collected in a dedicated, anonymized bariatric database of patients who underwent bariatric surgery between April 2023 and April 2024, at our Reference Center for Bariatric and Metabolic Surgery, Sf. Spiridon County Emergency Hospital Iași, Romania.

Thus, 83 obese patients were accepted for laparoscopic sleeve gastrectomy (SG) or Roux-en-Y gastric bypass (RYGB) procedures and were invited to participate in the study. Preoperative patient evaluation included laboratory tests, upper gastrointestinal endoscopy, abdominal ultrasound, chest radiography, as well as nutritional, cardiological, endocrinological, psychological, anesthesiologic, and pneumological (sleep apnea test) assessments. All patients in whom *Helicobacter pylori* infection was detected endoscopically underwent bacterial eradication treatment before surgery.

The inclusion criteria were to qualify for bariatric surgery, according to national guidelines (a BMI > 40 kg/m^2 or a BMI > 35 kg/m^2 and comorbidities, e.g. diabetes). The exclusion criteria were failure to attend the 12-month follow-up, therefore 65 patients remained in the study.

Other exclusion criteria were age under 18 years, inability to read or understand Romanian language, severe decompensated hepatic and renal disease, severe decom-

pensated cardiovascular pathology, uncontrolled psychiatric disease. Informed consent was obtained from all participants before the start of the study. The study was approved by the local ethics committee.

A questionnaire designed specifically for this study was distributed to patients before surgery and at the 12-month follow-up after surgery. A questionnaire designed specifically for this study was distributed to patients before surgery and at 12-month follow-up. It included questions in the form of reasons for seeking bariatric surgery. Participants in the study were asked to rate 14 items on a Likert scale from 1 (not important) to 5 (very important). The items were weight loss, taking less medication, improvement in comorbidities, having less pain, chances of being employed, improvements in social life, expectations to live longer, improved intimacy, improved self-esteem, improved fertility, improved ability to perform sports, having smaller cloth size, improved psychiatric health, and improved work performance. Participants were also asked to rate their top three reasons for seeking surgery, or their top three satisfaction items.

It was initially developed in English and subsequently translated and in Romanian by the two independent certified translators and the questionnaire were finalized and distributed to the patients in printed form.

In the questionnaire, participants were asked to self-report their age, height, weight, marital status, children, smoking, current goal, level of education, comorbidities and medication use. BMI (kg/m^2) was calculated based on reported height and weight.

Statistical Analysis. Categorical baseline characteristics and comorbidities were compared between surgery types using Pearson's chi-square test; Fisher's exact test was used when expected cell counts were <5. For the occupation variable (3-category distribution), a permutation-based chi-square test was applied due to sparse expected counts. Changes in binary questionnaire items between baseline and 12-month follow-up were assessed using McNemar's test (exact for small numbers of discordant pairs; otherwise asymptotic with continuity correction).

RESULTS

Statistical analysis. The study included a total of 65 patients who completed the preoperative questionnaire and had complete data at all preoperative and postoperative assessments. Of the total participants, 53 (81.5%) were female and 12 (18.5%) were male (fig. 1), indicating a clear predominance of female patients in the analyzed cohort (tab. I). Demographic characteristics

The mean age at the time of the preoperative assessment was 40.5 years. A total of 27 patients (41.5%) were under 40 years of age, while the majority of participants were over 40 years of age. Regarding family status, 36 patients (55.4%) had children and 29 (44.6%) did not have children. Regarding smoking, 23 patients (35.4%) were smokers, while 42 (64.6%) declared that they did not smoke.

Socio-professional characteristics. The analysis of occupational status showed that 30 patients (46.2%) were employed, 30 (46.2%) were unemployed, and 5 patients (7.7%) were retired. The educational level was relatively balanced: 33 patients (50.8%) had university education, and 32 (49.3%) had no university education. A total of 27 patients (41.5%) were under chronic drug treatment at the time of the

preoperative evaluation. Anthropometric characteristics

The preoperative body mass index (BMI) had a mean value of 43.39 kg/m², indicating severe obesity. The majority of patients, 42 (64.6%), had a BMI > 40 kg/m², while 23 (35.4%) had a BMI < 40 kg/m² at baseline. At 12 months after surgery, the mean BMI decreased significantly to 28.9 kg/m², reflecting a substantial improvement in weight status. The mean decrease in BMI between preoperative and postoperative periods was 14.42 kg/m². Also, the mean percentage of excess weight lost (%EWL) at 12 months was 66.04%, indicating a favorable surgical outcome.

Associated comorbidities. The main comorbidities reported preoperatively were: hepatic steatosis, dyslipidemia, hepatomegaly, arterial hypertension, obstructive sleep apnea syndrome (fig. 2). These results confirm the high prevalence of metabolic and cardiovascular diseases associated with severe obesity in the studied population.

Type of surgery. The types of bariatric surgery performed are shown in figure 3. (SG) was the most frequently used procedure, performed in 64.6% of patients, followed by (RYGB) in 35.4% of patients.

TABLE I.

Characteristics of the study population

Characteristic	Total (n=65)	RYGB (n=23)	SG (n=42)	p value
Age (years): <40	27 (41.5%)	7 (30.4%)	20 (47.6%)	0.179
Age (years): ≥40	38 (58.5%)	16 (69.6%)	22 (52.4%)	
BMI (kg/m²): <40	23 (35.4%)	6 (26.1%)	17 (40.5%)	0.246
BMI (kg/m²): ≥40	42 (64.6%)	17 (73.9%)	25 (59.5%)	
Children: Yes	36 (55.4%)	15 (65.2%)	21 (50.0%)	0.238
Children: No	29 (44.6%)	8 (34.8%)	21 (50.0%)	
Smoking: Yes	23 (35.4%)	5 (21.7%)	18 (42.9%)	0.089
Smoking: No	42 (64.6%)	18 (78.3%)	24 (57.1%)	
Occupation: Working	30 (46.2%)	14 (60.9%)	16 (38.1%)	0.044
Occupation: Retired	5 (7.7%)	3 (13.0%)	2 (4.8%)	
Occupation: Unemployed	30 (46.2%)	6 (26.1%)	24 (57.1%)	
Education: University degree	33 (50.8%)	15 (65.2%)	18 (42.9%)	0.085
Education: No university degree	32 (49.2%)	8 (34.8%)	24 (57.1%)	

Baseline characteristics were broadly comparable between surgery groups. No statistically significant differences were observed for age category, BMI category, parental status, smoking status, or education level (all p>0.05). Occupational status differed between groups (p=0.044), with a higher proportion of employed patients among the RYGB group and a higher proportion of unemployed patients among the SG group.

Overall, the most prevalent comorbidities at baseline were hepatic steatosis (83.1%) and dyslipidemia (70.8%), followed by

hepatomegaly (49.2%), sleep apnea (40.0%), and arterial hypertension (26.2%) (tab II). Sleep apnea was more frequent in the RYGB group compared with the sleeve gastrectomy group (56.5% *vs.* 31.0%, p=0.044), and hepatomegaly was also more frequent in the RYGB group (73.9% *vs.* 35.7%, p=0.003). Hepatic steatosis showed a non-significant trend toward higher prevalence in the RYGB group (95.7% *vs.* 76.2%, p=0.080), while dyslipidemia and arterial hypertension did not differ significantly between surgery types (p=0.680 and p=0.241, respectively).

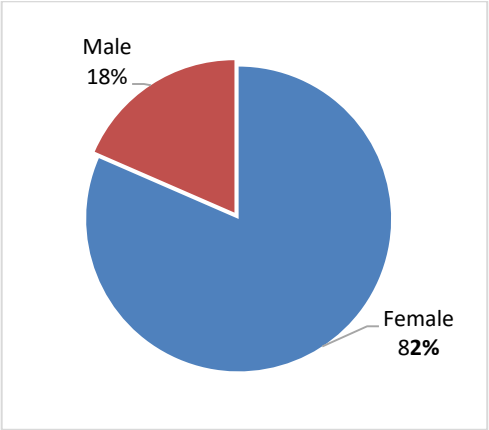

Fig. 1. Sex distribution of sample patients

TABLE II.
Distribution of comorbidities

Comorbidity	RYGB (n=23)	SG (n=42)	p value
Dyslipidemia	17 (73.9%)	29 (69.0%)	0.68
Sleep apnea	13 (56.5%)	13 (31.0%)	0.044
Arterial hypertension	8 (34.8%)	9 (21.4%)	0.241
Hepatic steatosis	22 (95.7%)	32 (76.2%)	0.08
Hepatomegaly	17 (73.9%)	15 (35.7%)	0.003

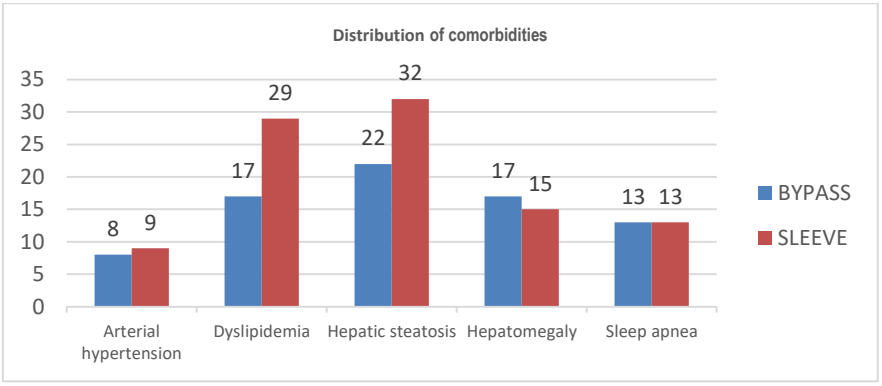

Fig. 2. Distribution of most common comorbidities in sample patients

The three most common reasons (fig. 3) for choosing bariatric surgery were weight loss (73.8%), followed by improved social life (50.8%) and improved self-esteem (43.1%). At 12 months, the most frequently endorsed items were weight loss (87.7%), improved self-esteem (63.1%), and improved co-morbidity (55.4%).

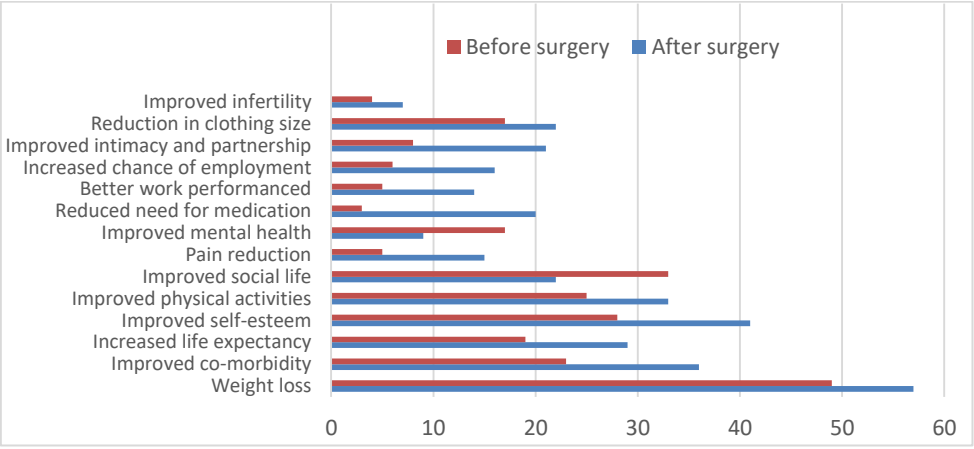

Fig. 3. The most important reason to seek bariatric surgery and items of greatest importance for satisfaction 12-month follow-up

TABLE III.

The most important reason to seek bariatric surgery

Reason	Before surgery	After surgery	p value
Weight loss	48 (73.8%)	57 (87.7%)	0.004
Improved co-morbidity	23 (35.4%)	36 (55.4%)	<0.001
Increased life expectancy	19 (29.2%)	29 (44.6%)	0.021
Improved self-esteem	28 (43.1%)	41 (63.1%)	0.031
Improved physical activity	25 (38.5%)	33 (50.8%)	0.077
Improved social life	33 (50.8%)	22 (33.8%)	<0.001
Pain reduction	5 (7.7%)	13 (20.0%)	0.021
Improved mental health	17 (26.2%)	9 (13.8%)	0.134
Reduced need for medication	2 (3.1%)	20 (30.8%)	<0.001
Better work performance	5 (7.7%)	12 (18.5%)	0.118
Increased chance of employment	6 (9.2%)	16 (24.6%)	0.021
Improved intimacy and partnership	8 (12.3%)	21 (32.3%)	0.002
Reduction in clothing size	14 (21.5%)	23 (35.4%)	0.110
Improved fertility	5 (7.7%)	7 (10.8%)	0.688

From baseline to 12-month follow-up, several motivations / satisfaction items changed significantly (tab. III). The proportion endorsing weight loss increased (73.8% to 87.7%, p=0.004), as did improved co-morbidity (35.4% to 55.4%, p<0.001), increased life expectancy (29.2% to 44.6%, p=0.021), improved self-esteem (43.1% to 63.1%, p=0.031), pain reduction (7.7% to 20.0%, p=0.021), increased chance of employment (9.2% to 24.6%, p=0.021), and improved intimacy/partnership (12.3% to 32.3%, p=0.002). Reduced need for medication also increased (3.1% to 30.8%, p<0.001). In contrast, endorsement of improved social life decreased from baseline to 12 months (50.8% to 33.8%, p<0.001). No statistically

significant changes were observed for improved physical activity, improved mental health, better work performance, reduction in clothing size, or improved fertility (all $p>0.05$).

DISCUSSION

The results of the present study show that weight loss was one of the most important reasons for patients to choose bariatric surgery, as well as one of the main factors of satisfaction at 12 months postoperatively. This result is expected and is consistent with data previously reported in the literature, which indicate weight loss as the main determinant of the decision to resort to bariatric surgery (10). In our study, improved social life and, increased self-esteem occupied the second and third places in the hierarchy of reasons why patients resorted to bariatric surgery. Regarding postoperative satisfaction, weight loss is important for patients and improved self-esteem was a frequently mentioned factor. This finding supports the results of other studies that have shown that self-esteem plays an essential role in the subjective assessment of the success of bariatric surgery (16). The increase in self-esteem is likely the result of both significant weight loss and improved perceptions of body image and social integration. However, existing data suggest that improvements in self-esteem may occur early after surgery, even before significant weight loss is achieved. Previous studies have shown a significant increase in self-esteem just a few months after surgery, suggesting the existence of additional psychological mechanisms independent of weight loss (17). In addition, weight loss has been shown to be associated with significant increases in social and professional relationships, which may indirectly contribute to increased self-esteem (16). Obesity-related comorbidities were an important reason for resorting to bariatric surgery, and they were among the top three criteria for postoperative satisfaction. This observation can be explained by the fact that the population included in the present study presented important co-morbidities that improved or healed after weight loss. Improvements in quality of life after surgery have been reported as early as 3 months postoperatively in some studies (18). However, studies with longer follow-up periods suggest that these improvements may decline over time (19).

CONCLUSIONS

It is important for patients to understand the importance of lifestyle changes and maintaining a healthy lifestyle after surgery to achieve successful weight loss and avoid weight regain. While some patients are well informed, others may need additional counseling, as weight regain after bariatric surgery has been shown to be unexpected, and patients have reported being unprepared for, and having unrealistic expectations of weight loss (20). A future challenge will be to effectively identify patients who need additional support before, as well as after surgery. To further address the effect of expectations on outcomes such as weight loss and weight maintenance after bariatric surgery, prospective studies with repeated and long-term follow-up of patients, including men, who have undergone different types of bariatric surgical procedures, are needed.

DIAGNOSTIC AND PROGNOSTIC UTILITY OF COMPLETE BLOOD COUNT-DERIVED INFLAMMATORY MARKERS AND C-REACTIVE PROTEIN IN PENILE CANCER (Abstract): Systemic inflammatory indicators obtained from standard blood tests have garnered heightened interest as prospective diagnostic and prognostic instruments in oncological urology. **Materials and methods:** This study assessed the diagnostic efficacy of complete blood count-derived inflammatory indices and C-reactive protein (CRP) in individuals with penile cancer. A total of 38 individuals with penile cancer were compared to 38 control participants receiving surgery for benign scrotal conditions. **Results**: Notable disparities were identified between the two groups for baseline characteristics. Patients with penile cancer were much older and had reduced blood hemoglobin levels and elevated serum creatinine values in comparison to controls. All assessed inflammatory markers were markedly enhanced in the cancer cohort, suggesting an increased systemic inflammatory load. Mean CRP levels were significantly elevated in patients with malignancy, accompanied by markedly higher neutrophil-to-lymphocyte ratio (NLR), monocyte-to-lymphocyte ratio (MLR), systemic immune-inflammation index (SII), systemic inflammation response index (SIRI), and aggregate index of systemic inflammation (AISI). An examination of the ROC curves for inflammatory markers revealed statistically significant differences between groups. The NLR exhibited strong discriminating capacity for penile cancer, with an area under the curve (AUC) of 0.829. CRP had significant diagnostic efficacy (AUC 0.700). Conversely, composite indices such as SIRI and AISI showed relatively little discriminatory ability, with AUC values of 0.694 and 0.697, respectively. **Conclusions:** Individuals with penile cancer exhibit markedly increased systemic inflammatory markers in comparison to controls. Among the assessed indices, NLR and CRP demonstrated the greatest diagnostic efficacy, whereas more complex composite indices provided minimal additional differentiation. **Keywords:** PENILE CANCER, INFLAMMATORY MARKERS, NEUTROPHIL-TO-LYMPHOCYTE RATIO, C-REACTIVE PROTEIN, SII, AISI, SIRI.

INTRODUCTION

The early identification of reliable diagnostic and prognostic biomarkers remains a priority for improving cancer patient stratification, optimizing treatment decisions, and enhancing long-term survival outcomes. Recent studies have shifted attention to blood-based biomarkers derived from routine laboratory tests. These markers possess the advantage of being readily accessible,

minimally invasive, and cost-efficient compared to tissue-based molecular assays. According to Czajkowski *et al*., the neutrophil-to-lymphocyte ratio (NLR) has attracted substantial attention for its potential to reflect systemic inflammation and the interplay between tumor biology and immune response (1). In penile squamous cell carcinoma (PSCC), elevated NLR has been repeatedly associated with poorer overall survival (OS), recurrence-free survival (RFS), and cancer-specific survival (CSS) (2). Systemic inflammation markers extend beyond NLR. C-reactive protein (CRP), for example, is synthesized by hepatocytes in response to interleukin-mediated pathways such as IL-6 and IL-1β, which trigger transcriptional activation mechanisms involving C/EBP proteins (1). While CRP is classically associated with infection or trauma, elevated levels have been observed across multiple malignancies. In penile cancer, Qin *et al*. propose that high CRP values might be linked to worse prognosis in advanced disease stages (3). Altogether, this framing underscores why a systematic synthesis examining complete blood count-derived inflammatory markers alongside CRP can provide tangible benefits: clarifying contradictory findings in the literature; quantifying predictive value across diverse patient groups; and exploring how these readily available metrics interface with disease management algorithms currently applied to penile cancer patients (4). We aimed to compare complete blood count (CBC)-derived inflammatory markers and CRP levels between patients with penile cancer and a control group.

MATERIALS AND METHODS

Data of patients who were diagnosed with PSCC who underwent penile amputation at “Dr. C.I. Parhon” Clinical Hospital, Iasi, and Neamt County Hospital between January 2021 and December 2025 were collected retrospectively.

Penile amputation was performed after confirmation of neoplasia by a previous biopsy in accordance with the recommended guidelines. The blood sample was taken before surgery. Patients with disorders that could influence inflammatory markers, including additional malignancies, active or chronic infections, immunosuppressive diseases, systemic inflammatory conditions, the use of immunosuppressive medications, and renal or hepatic dysfunction, were excluded from the study. The control group was formed by patients who presented for benign scrotal pathology, namely hydrocele, in a number equal to that of the study group, in the order in which they presented for surgical treatment in the last period of the study. From both groups, we collected data including age at the time of surgery, complete blood count, C-reactive protein, and serum creatinine. The CBC-derived inflammatory markers have been calculated as follows: NLR = neutrophil count / lymphocyte count, MLR = monocyte count / lymphocyte count, Systemic Immune-Inflammation Index (SII) = platelet / × neutrophil-to-lymphocyte ratio, Systemic Inflammation Response Index (SIRI) = (neutrophil count × monocyte count) / lymphocyte count; Aggregate Index of Systemic Inflammation (AISI) = (Neutrophil count × Monocyte count × Platelet count) / Lymphocyte count (5-7).

The Mann-Whitney U test was employed to compare each parameter between groups. Data were presented as mean ± standard deviation and median; $p < 0.05$ was accepted as statistically significant. The area under the receiver operating char-

acteristic (ROC) curves was assessed for the markers that were significantly different between the two groups.

Approval was obtained from the hospital Ethics Committee (Approval No.1372/09-FEB-2026). Statistical analysis was performed using the *Statistical Package for the Social Sciences version 26.0* (SPSS Inc., Chicago, IL, USA).

RESULTS

We included a total of 38 patients diagnosed with penile cancer and 38 subjects in the control group. Comparative analysis demonstrated statistically significant differences between the two groups for several baseline clinical and laboratory parameters, including mean age, serum hemoglobin levels, and serum creatinine levels. Patients in the cancer group were significantly older and exhibited lower hemoglobin concentrations and higher serum creatinine levels compared with controls.

Regarding systemic inflammatory status, marked differences were observed between the two groups. All evaluated inflammatory markers showed statistically significant elevations in the cancer group compared with the control group (tab. I). These findings suggest a substantially higher inflammatory burden among patients with malignancy.

TABLE I.

Comparison of characteristics between the two groups

Parameter	Penile cancer (n=42)	Control (n=98)	p
Mean age (years), SD	65.71 (±10.79)	42.65(±13.92)	**0.001**
Serum Hemoglobin (g/dl)	13.12 (±2.61)	14.77 (±1.02)	**0.0013**
Serum creatinine mg/dl	1.58 (±0.13)	0.92 (±0.16)	**0.05**
CRP (mg/L)	13.64 (±12.80)	2.98 (±2.84)	**0.0069**
NLR	3.64 (±2.18)	1.84 (±0.62)	**0.001**
MLR	0.41 (±0.23)	0.29 (±0.12)	**0.007**
SII	1001.88 (±766.08)	468.10 (±184.64)	**0.001**
SIRI	2.42 (±1.94)	1.39 (±0.6)	**0.003**
AISI	718.39 (±736.23)	313.15 (±188.85)	**0.003**

To further evaluate the discriminatory performance of the inflammatory markers that differed significantly between the two groups, we performed receiver operating characteristic (ROC) curve analyses, focusing particularly on CRP and NLR. The ROC analysis revealed that NLR demonstrated good discriminatory ability, with an area under the curve (AUC) of 0.829. CRP showed a moderate discriminatory capacity, with an AUC of 0.700.

In contrast, the composite indices SIRI and AISI exhibited relatively poor discriminative performance, with AUC values of 0.694 and 0.697, respectively. These results are illustrated in Figure 1. During the study, we did not record any patient deaths. Pathological examination revealed that 60.52% (n=23) have been classified as T1, 31.57% (n=12) as T2, and 7.89% (n=3) as T3.

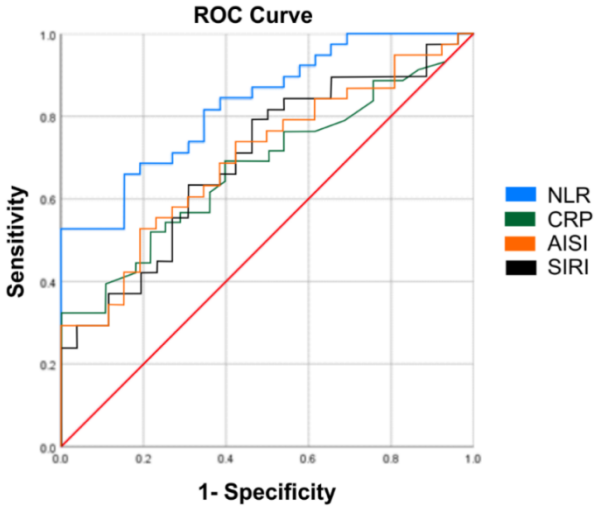

Fig. 1. ROC analysis of the inflammatory markers

DISCUSSION

To investigate oncological diseases, markers are used that, although effective, are often too expensive for current practice (8). On the other hand, CBC-derived inflammatory markers are cheap and have proven useful in certain types of cancer (9, 10). CBC profiles, including absolute counts and subtype proportions, provide a window into the systemic immune status of patients with penile squamous cell carcinoma. Distinct white blood cell subtypes, neutrophils, lymphocytes, monocytes, and platelets, reflect different facets of inflammation and immunity, and when these parameters shift in characteristic ways, they can mark progression or prognosis in PSCC. Neutrophils, as primary components of the innate immune system, play a dual role in cancer. Tumor-associated neutrophils can be recruited via chemokine gradients established within the microenvironment and may contribute to tumor initiation and growth by activating cancer cells or suppressing cytotoxic lymphocyte function. Such suppression could manifest as elevated peripheral neutrophil counts relative to lymphocytes, leading to an elevated NLR. The elevation of NLR itself can arise from several physiological scenarios: increased neutrophil counts coupled with reduced lymphocyte numbers; increased neutrophils without lymphocytic changes; or diminished lymphocytes without altered neutrophils (11).

Elevated NLR has been linked not only to disease-specific mortality but also correlates with nodal stage severity, offering a potential bridge between routine hematology results and staging models traditionally constructed from imaging or intraoperative findings (12). Lymphocytes are central to immune surveillance against malignancy. Their depletion reduces the capacity to mount adaptive immune responses and is linked to enhanced tumor progression due to weakened control over aberrant cells. A reduction in circulating lymphocytes relative to platelets, the platelet-to-lymphocyte ratio (PLR), has been suggested as a marker for poor prognosis in diverse cancers

because it reflects both diminished immunity and increased platelet-mediated tumor support functions (13). According to Steffens *et al.*, combining NLR with CRP levels has shown potential in improving predictive ability for poor outcomes, especially in non-metastatic patients who nonetheless harbor aggressive local or regional disease patterns (14).

Elevated monocyte-to-lymphocyte ratio (MLR), a CBC-derived value, is another CBC-derived value proposed as an independent prognostic factor across cancers (13). In PSCC research cohorts, reduced LMR may indicate a skewing toward a microenvironment dominated by macrophages, which typically favors tumor facilitation over elimination. Platelets themselves transport proangiogenic and antiangiogenic factors within their granules and microparticles (15).

CRP belongs to the pentraxin family of proteins and is categorized as an acute-phase reactant, with production predominantly occurring in hepatocytes under stimulation by proinflammatory cytokines such as interleukin-6 (IL-6), interleukin-1β (IL-1β), and tumor necrosis factor-α. Under conditions of infection, trauma, or malignancy, circulating CRP levels can rise profoundly, sometimes exceeding baseline by over 1000-fold, in a relatively short timeframe (16, 17). In PSCC studies investigating prognostic markers, threshold values above 15 mg/L have been associated with increased nodal disease incidence and reduced cancer-specific survival (18). Lower but persistently elevated ranges, for example above 5 mg/L, have been incorporated into multi-factor prognostic scoring models alongside surgical margin status and pathological stage to stratify patient mortality risk (16).

Tumor-associated macrophages, malignant keratinocytes, and reactive stromal fibroblasts secrete IL-6 continuously, maintaining hepatic CRP synthesis without reverting to basal levels (1). Unlike infection-mediated acute peaks that resolve as pathogens are cleared, malignancy-associated CRP elevation can remain stable or fluctuate at moderately high levels depending on ongoing tumor activity and metastatic spread. This chronicity imbues CRP readings with prognostic relevance: persistent concentrations above modest thresholds have correlated with reduced disease-specific survival and advanced pathological stages in genitourinary cancers including PSCC (19). In patients with PSCC, correlations have been observed between elevated pre-treatment CRP and adverse clinical indicators such as extranodal extension or bilateral pelvic lymph node metastasis (20).

Elevated neutrophil-to-lymphocyte ratio (NLR) values have been repeatedly associated with adverse outcomes, such as reduced overall survival (OS) or cancer-specific survival (CSS), though the strength of these associations may diminish after adjustment for established pathological factors, such as tumor grade, lymph vascular invasion, and clinical nodal status (21). The platelet-to-lymphocyte ratio (PLR) shows similar trends, with higher values generally observed among individuals with extranodal extension or advanced TNM staging. In smaller PSCC cohorts, PLR elevation is associated with worse OS, complementing the picture presented by NLR but with a slightly different biological emphasis, capturing platelet-driven microenvironment changes coupled with adaptive immune suppression. While precise cut-off thresholds vary across reports due

to population and assay differences, values exceeding 133.5 have been proposed via receiver operating characteristic curve analysis for stratifying risk before surgical intervention (13).

While the systemic indices discussed earlier capture host inflammatory status in a relatively accessible way, they remain indirect proxies for intratumorally events. Recent advances in molecular pathology have reclassified penile neoplasms into discrete biological subtypes based on HPV status, gene mutations, and protein expression profiles (12). By overlaying CBC- or CRP-derived inflammatory metrics onto these molecular categories, it becomes possible to examine whether specific genomic contexts consistently produce certain systemic inflammatory phenotypes. For example, an elevated neutrophil-to-lymphocyte ratio (NLR) might align more with TP53-mutated, HPV-negative tumors characterized by high PD-L1 expression, reflecting immunosuppressive microenvironments that weaken adaptive immune surveillance (22).

CONCLUSIONS

Penile squamous cell carcinoma presents unique challenges due to its multifactorial etiology and the intricate interplay between tumor biology and host immune responses. The integration of complete blood count-derived inflammatory markers such as NLR, platelet-to-lymphocyte ratio, and MLR, alongside C-reactive protein measurements, offers a promising avenue for enhancing prognostic assessment and clinical management. These biomarkers provide accessible, minimally invasive, and cost-effective tools that reflect systemic inflammation and immune dysregulation associated with tumor progression, nodal metastasis, and survival outcomes.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

GIANT UTERINE MYOMA AND OVARIAN MYOMA- ASSOCIATION OF TWO RARE ENTITIES - CASE REPORT AND LITERATURE REVIEW (Abstract): Uterine myomas are the most common benign tumors of female reproductive system. They affect 25% of women of reproductive age. Giant uterine myomas are quite rare and are a challenge both for a complete diagnosis and for surgical management. Extra-uterine myomas are rare and they usually appear in the genitourinary tract (ovaries, vulva, broad ligament, round ligament, urethra). Primary ovarian leiomyoma is one of the rarest solid tumors of the ovary accounting for 0.5%–1% of all benign ovarian neoplasms. We report a 45-years-old nulliparous woman who came with abdominal distension and fatigue for several months. Abdominal-pelvic ultrasound and computer tomography showed a large myoma-like mass that filled the pelvis and abdomen. The diagnosis of giant uterine myoma was established and after careful discussion with the patient total hysterectomy was proposed. Surgery confirmed the diagnosis of a giant uterine myoma with several parasitic omental blood supplies. An additional ovarian myoma was discovered and total hysterectomy with right adnexectomy was performed. Our case stresses several clinical points that should be kept in mind before planning a surgery for a giant myoma - the possible presence of parasitic blood vessels and adherences which can pose some difficulties for the surgical team and the coexistence of different pathologies masked under the size of the tumor. It is important before planning a surgery to discuss with the patient the possibility to adapt the surgery according to associated pathology. **Keywords:** UTERINE LEIOMYOMA, GIANT LEIOMYOMA, GIANT MYOMA, LARGE MYOMA, OVARIAN MYOMA.

Uterine myoma is the most common benign tumors of female reproductive system. It affects 25% of women of reproductive age (1). Giant uterine myomas are quite rare and are a challenge both for a complete diagnosis and for surgical management. The challenge in diagnosis comes from their size, as they can hide other associated conditions, which sometimes are discovered during surgery and require changing the initial surgical plan. We present a case with two rare associated entities: a large uterine myoma associated with an ovarian fibroma.

CASE REPORT

A 45-year-old nulliparous woman comes to gynecological exam for a progressive increase of the abdomen and lower abdominal pain. Her medical history was normal, and she has no pregnancies. Her vital signs were all within normal limits. Clinical examination reveals the distension of the abdomen and the presence of a firm not tender lumpy abdominal and pelvic mass (fig. 1). A rectal examination was performed (the patient being a virgin) and it revealed a very large firm central mass filling the pelvis and abdomen. It was difficult to specify the origin of tumor. The results of routine laboratory testing were normal. Transabdominal ultrasound confirmed the presence of a large tumor highly suggestive of a uterine leiomyoma localized intramural and subserous. Bilateral ovaries could not be detected. An abdominal and pelvic computed tomography (CT) showed a large mass, approximately 25/20/13 cm in size, occupying the abdomen from pelvis to the upper abdominal cavity.

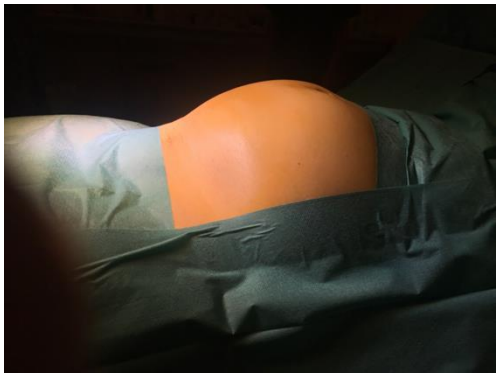

Fig.1. Clinical picture of the abdomen shows an important distension of the whole abdomen.

In the light of the clinical examination, the routine laboratory findings and US and CT results, the preoperative diagnosis was giant uterine myoma and after the informed consent of the patient was obtained, total abdominal hysterectomy was proposed.

Laparotomy revealed a large multilobular tumor originating from the uterus occupying the whole abdomen. Adhesions and parasitic vessels between the mass, omentum and descending colon were present. After careful dissection of the adhesions the examination of the ovaries revealed normal left ovary and a 3-cm myoma-like tumor at the right ovary. Because this tumor and giant uterine myoma total hysterectomy and right adnexectomy were performed. The postoperative evolution was uneventful, and the patient was discharged three days after the operation in excellent condition. The removed specimen was 4.5 kg in weight and size was 25/20/12 cm (fig. 2). Microscopic examination revealed a multilobulated leiomyoma, endometrial polyp and ovarian myoma.

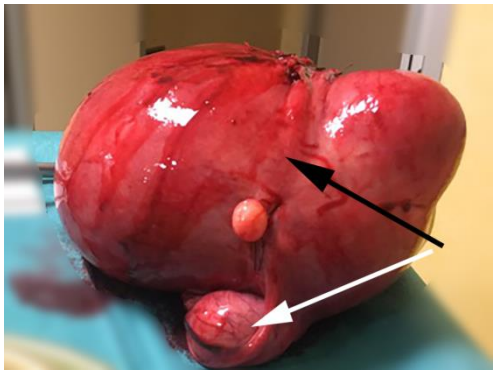

Fig.2. Surgical specimen- black arrow - the whole uterus, white arrow the ovarian myoma.

DISCUSSION

Uterine leiomyomas are common benign tumors affecting 25% of women of reproductive age (1). Uterine myoma can be asymptomatic or can cause a variety of symptoms, including abnormal bleeding,

pain, infertility, miscarriage and compression on neighboring organs. Although the size of leiomyoma varies from microscopic to large, giant uterine myomas are uncommon. Giant uterine myomas are almost always symptomatic because of the tumor bulk-related symptoms.

Extra-uterine myomas are rare and present a great diagnostic challenge. They usually appear in the genito-urinary tract (ovaries, vulva, broad ligament, round ligament, urethra) (2). Ovarian fibromas are benign ovarian tumors of sex cord stromal origin. Primary ovarian leiomyoma is one of the rare solid tumors of the ovary, accounting for 0.5%–1% of benign ovarian neoplasms (3). Ovarian fibroma is generally asymptomatic and seen in women >50 years of age. Most ovarian leiomyomas are small, measuring only a few millimeters to centimeters in diameter but sometimes they can get larger and the ovary may become completely absorbed by the tumor (4). The differential diagnosis includes ovarian fibroma-thecoma, cellular fibroma, and sclerosing stromal tumor leiomyosarcoma. Ovarian fibroma is benign and complete surgical resection is the treatment.

A useful tool for diagnosis of uterine or ovarian myoma is the ultrasound examination where typically a myoma has whorled pattern appearance with variable echogenicity, depending on the presence of degeneration and calcification. In some cases, cystic degeneration with extensive edema forming cystic fluid-filled spaces can occur and the diagnosis can be more difficult to establish. Computed tomography and magnetic resonance imaging can also be used to diagnose fibromas.

The association of ovarian myoma and uterine myoma was reported by Doss et al. (5). According to our knowledge this is the first case that associates a giant uterine myoma with ovarian myoma and endometrial polyp. Our case stresses several clinical points that should be kept in mind in cases with giant uterine myoma. First, as leiomyomas enlarge, they can outgrow their blood supply and several parasitic blood vessels can appear from the structures it is adherent to. Such structures include the omentum, common iliac artery and inferior mesenteric artery (6, 7). Both parasitic vessels and adhesion can pose some difficulties to surgical team during surgery. Various types of degeneration such as hyaline, cystic, myxoid or red degeneration may appear in cases of giant myoma (8,9). These degenerations give atypical appearances and can cause confusion in diagnosis with imaging techniques like USG, CT, and MRI. The most frequent confusion that could appear is with an ovarian tumor (10,11). The final diagnosis can be made either intraoperative or histologically. Also imaging technique can in some cases miss some associated pathologies due to the size of the giant myoma. The patients should be informed about this possibility and about the need for adapting or changing the planned surgery to attempt a complete recovery.

CONCLUSIONS

Giant uterine myoma needs a careful preoperative exploration, as its size can sometimes hide other associated pathologies. To prevent discovering these pathologies during the surgery and to avoid surgical management without patient's consent, it is appropriate to carefully explore all the cases. Even so it is important to discuss with the patient and to inform him that due to the size of the tumor it is possible to change the surgical plan.

WHEN AND HOW TO CORRECT VITAMIN D DEFICIENCY?

In the last teen years, more than 30,000 articles regarding the importance of vitamin D in some physiological process, have been published worldwide. Now, we know the importance of vitamin D in immunoregulation, insulin production, cellular growth and cardiovascular protection. What we don't really know is: what is the optimal level of vitamin D to cover all needs of the tissues that have vitamin D receptor (VDR)? For human well-being we need at least 20 ng/mL (the cut-off for treatment) and Endocrine Society it recommended achieving more than 30ng/mL with the preferred range of 40-60 ng/mL. Recommendations are: infants up to 1 year, 400-1,000 IU/day, for children over one year 600-1,000 IU/day, and for adults 1,500-2,000 IU/day. There are no reports regarding the intoxication with vitamin D in adults (Pludowski P, Holick MF, Grant WB, et al. Vitamin D supplementation guidelines. *Journal of Steroid Biochemistry and Molecular Biology*. doi: 10.1016/j.jsbmb.2017.01.021. Epub 2017 Feb 12).

THE MEDITERRANEAN DIET IMPACT ON PREVENTION AND TREATMENT OF COGNITIVE DECLINE (Abstract): The world's population aged over 60 years is predicted to double in the next 50 years. Increased age makes us vulnerable to various neurodegenerative pathologies among them cognitive impairment and dementia. The economic and social burden of caring for persons with cognitive decline is increasing, and to date there are no effective pharmacologic agents to prevent or treat the disease or even its precursor stages. Identifying simple and effective interventions, like modifiable risk factors to prevent cognitive decline and dementia is likely to be an important strategy for delaying the onset, and reducing the number of patients is a major public health priority. There is growing evidence that diet -a modifiable risk factor- could be one component of an effective prevention strategy against cognitive decline, although no firm conclusion can be drawn at this point. A healthy Mediterranean diet (MeDi), rich in fruit, vegetables, whole grains, nuts, olive oil, and fish may be neuroprotective. Greater adherence to the MeDi is associated with slower rate of cognitive decline and lower risk of cognitive impairment and dementia, but findings are conflicting, mainly due to significant heterogeneity between studies in terms of populations studied and methods used to assess diet and cognition. All these reasons highlight the need for randomized clinical trials and for further research. **Keywords**: COGNITIVE IMPAIRMENT, NUTRITION, MEDITERRANEAN DIET.

Aging is a normal and physiological process. Genetic studies claim that we are born with a genetic determined cognitive reserve which is affected as we get older by environmental and external factors resulting in a decline. Epidemiological studies predict that the number of persons affected by cognitive decline will double every 20 years and reach 106.8 million, affecting 1 out of 85 persons by 2050. Therefore, is a growing public health concern with significant socioeconomic burden, being one major cause of death and disability worldwide (1).

Cognitive impairment can be influenced by several factors and the potential effect of nutrition has become a topic of increasing scientific and public interest (2). In

recent years, there has been increasing evidence supporting the role of nutrition in and that to achieve a benefit, an intervention would likely need to be started in the preclinical stage. Emerging evidence suggests an association between dietary habits and cognitive performance (3). Nutrients and diets, together with other aspects of daily living (such as exercise), can affect multiple brain processes by regulating neurotransmitter pathways, synaptic transmission, membrane fluidity and upregulating genes for maintaining synaptic function and plasticity (4).

A common approach to explore the impact of nutrition is studying dietary patterns comprising combinations of nutrients and foods. A frequently studied dietary pattern is the Mediterranean diet, which is rich in fruits and vegetables and unsaturated fatty acids and has been proven to have vascular and anti-inflammatory benefits and may be neuroprotective (5). It was first described by dr. Walter Willet from Harvard University in 1990 and recognized as UN cultural patrimony in 2013. Its definition consists in recommendations regarding the number of portions per day of different classes of nutrients. It favors the consumption of whole grains, fruits and vegetables, olive oil, fish, nuts and dairy over red or processed meat products and refined sweets. It also recommends increased water consumption and 1 or 2 glasses of red wine per day. The Mediterranean dietary pattern refers not only to the type of food consumed, but also to lifestyle and the social customs associated with the way of eating. It therefore seems reasonable to assume that this pattern of healthy eating can modify cognitive status and reduce the prevalence of cognitive impairment, and mood disturbances in the elderly population (6).

THE ADHERENCE TO THE MEDITERRANEAN DIET

The Mediterranean Diet was largely studied due to its effect in many pathologies. Cognitive decline means brain aging which involves neurodegeneration with loss of synapses and neurons, increased oxidative stress, inflammation and vascular impairment. The primary foods of the Mediterranean diet contain bioactive nutrients and phytochemicals like polyphenols, flavonoids, vitamins, minerals and fiber, arginine and antioxidants with anti-inflammatory proprieties and neuroprotective effect (7). The fish and olive oil contain a lot of omega 3 acids (polyunsaturated fatty acids), part of the neural membrane functioning, increase the activity of antioxidation enzymes, protecting against oxidative stress, neuronal death and the formation and aggregation of amyloid in the brain (8).

Prospective studies have shown that populations with higher adherence to MeDi exhibit lower risk of cardiovascular diseases (9). Reduced inflammation and improved endothelial function produce vasodilatation and increased cerebral blood flow, reducing oxidative stress and neuronal cell death. Interventional studies have reported improvements to blood pressure, lipid profiles, insulin sensitivity, CRP levels and oxidative stress. (10).

Greater adherence to the Mediterranean diet has been associated with a lower rate of cognitive decline in many observational and interventional studies (11). The international recommendations for globally applicable dietary guidelines were translated into the Healthy Diet Indicator (HDI) by the World Health Organization (WHO) in 1990 (12). The HDI based on initial WHO recommendations has been associated with a lower prevalence of cognitive impairment. There-

fore, the Consortium on Health and Ageing: Network of Cohorts in Europe and the United States (CHANCES) which included 3 population-based cohorts: Survey in Europe on Nutrition and the Elderly, a (SENECA), Rotterdam Study (RS), Nurses' Health Study (NHS) totaling 21,837 men and women from Europe and US concluded that a higher HDI score was not related to reduced rates of cognitive decline in European and American older adults (13).

Beside many studies regarding the association between Mediterranean style of eating and cognitive decline, there are a few meta-analyses which gather and select the most important data about this subject. Researchers from Mayo Clinic, USA, screened 664 studies through November 2012, aiming to determine whether there is an association between the Mediterranean diet (MeDi) and cognitive impairment. Only five studies met the eligibility criteria and showed that higher adherence to the MeDi reduced the risk of mild cognitive impairment with 33%. Results also suggested that a higher adherence to the MeDi is associated with a significant reduced risk of developing Alzheimer disease, and a reduced risk of progressing from mild cognitive impairment to dementia (14).

Living on a Mediterranean diet also reduces the risk of stroke, depression, cognitive impairment and Parkinson disease. Higher adherence to MeDi has protective action and is consistently associated with reduced risk for stroke, mainly ischemic and in the male population. Moderate adherence was linked to reduced risk for depression (15). Not living in the Mediterranean area has not been an impediment for the benefit of MeDi on cognition. Lower adherence to a Mediterranean diet was associated with higher AD and mild cognitive impairment compared to healthy subjects in an Australian population (16). An analysis conducted in a group of healthy elderly Swedish men and women, showed that adherence to MeDi was positively associated to healthier cognitive aging, even though no association was found between Mediterranean score and cognitive function or brain volume measured by magnetic resonance (17).

Not all studies favor the benefit of MeDi. For example, results from the cognitive sub-study of the Women's Health Study reported no association of the Mediterranean diet with cognitive decline. Differences in methodologies used to assess adherence, different sample size, the heterogeneity of groups or populations tested and poor reliability of food questionnaires, among other factors may be the reason why some studies have found no correlation between adherence to a Mediterranean diet and delayed or reduced cognitive decline (18).

PREVENTION WITH THE MEDITERRANEAN DIET

Successful aging depends on the homeostatic reserves of different physiological systems. Recent literature states that MeDi has also effects on cognitive frailty. This novel entity represents a critical intermediate status of the aging process that is at increased risk for negative health-related events and it is starting to be investigated also in association with nutrition (19). There is not a clear understanding of the pathways converging into frailty, but it seems that the losses imposed by ageing, the impact of acute or chronic disease, and the own genetic endowment of the individual may have important roles (20). The potential for reversibility of frailty and its

different phenotypes suggests that these clinical features may be important for secondary prevention in neurodegenerative diseases. Studies have reported an inverse association between adherence to a Mediterranean diet and lifestyle and prevalence of frailty (21).

Preventing cognitive decline is the subject of recent research. One of them investigated the association between MeDi and the prevention of mild cognitive impairment (MCI) and the progression from MCI to Alzheimer disease (AD) in a multiethnic community in New York. 1,393 cognitively normal participants were included from who 275 developed MCI and 106 were diagnosed with AD for 4.5 years. Subjects that consumed MeDi had 28% less risk of developing MCI and 48% less risk of developing AD compared to control. In the end, there was a significant protective effect of MeDi against MCI and AD, and even a reduced risk of MCI conversion to AD. Studies looked deeper into the effects of MeDi on the domains of cognitive function of healthy older adults, respectively on memory and executive function. In a met analysis with 41,492 participants where the primary outcome was cognitive function, but divided into domains of memory and executive function results revealed a significant association between MeDi and older adults' episodic memory and global cognition, but not working or semantic memory. Also, compared with controls, the MeDi improved delayed recall, working memory and global cognition, but not episodic memory, immediate recall, attention, processing speed or verbal (22).

A study published this year investigated the associations of MeDi and its components with magnetic resonance imaging measures of cortical thickness for the four lobes separately and averaged. Higher MeDi score was associated with larger frontal, parietal, occipital, and average lobar cortical thickness and higher adherence to MeDi was associated with larger cortical thickness. While higher legume and fish intakes were associated with larger cortical thickness, especially parietal and precuneus, higher carbohydrate and sugar intakes were associated with lower entorhinal cortical thickness. This study opens new paths for research, but these novel findings need cross-sectional and prospective studies for validation (23).

Another proposed neuroprotective dietary pattern, the Mediterranean-DASH diet Intervention for Neurodegeneration Delay (MIND diet), has been recently described. The MIND diet is a modified version of MeDi but incorporates additional foods based on current evidence in the study of the effect of diet on dementia. In some population-based studies MIND score was more predictive of cognitive decline than MeDi score, and higher MIND scores were associated with lower risk of Alzheimer disease. These results show that greater adherence to MeDi and MIND diet patterns are associated with better overall cognitive function in older adults and lower odds of cognitive impairment, which could have important public health implications for preservation of cognition during aging (24).

THE THERAPEUTIC ROLE OF THE MEDITERRANEAN DIET

The literature available today is also focused on nutritional therapy or intervention, in delaying the neurodegeneration processes with various nutrients and diets. Regarding this new goal, a recent parallel-group randomized clinical study investigated 447 participants on a Mediterranean diet

if it influences cognitive status compared with a control diet for 6 years. The *Prevención con Dieta Mediterránea* (PREDIMED) study used neurocognitive testing at inclusion and at the end of the study, among which the Mini-Mental State Examination, Rey Auditory Verbal Learning Test (RAVLT), Wechsler Scale and the Color Trail Test (CTT). The participants were randomly assigned to MeDi supplemented with extra virgin olive oil (1L/week), MeDi supplemented with mixed nuts (30 g/d), or a control low fat diet. The follow-up was available only to 334 participants after intervention and data showed that the group allocated to MeDi plus olive oil scored better on the RAVLT, MMSE and Color Trail Test compared with controls; no between-group differences were observed for the other cognitive tests. The MMSE and CTT scores were also higher for participants allocated to MeDi and nuts versus control. In the end, the investigators concluded that, although not in all cognitive tests, a Mediterranean diet supplemented with olive oil or nuts is associated with improved cognitive function per se, but also compared with a low-fat diet (25).

Furthermore, actions are taken in the medical world to use diets as interventional strategies in treating different diseases. This year, the BRIDGE (Building Research in Diet and CoGnition) randomized controlled trial started and aims to investigate the effect of MeDi, with and without weight loss, on cognitive functioning in obese older adults (BMI ≥ 30 kg/m^2 and ≤ 50 kg/m^2, age ≥ 55 years). They will be randomized in a 2:2:1 allocation scheme to: Typical Diet Control; MeDi alone, without weight loss; or MeDi lifestyle intervention to promote weight loss and weight loss maintenance. Both MeDi intervention groups will meet for one individual session and 27 group sessions over an 8-month period. Individuals in the control group will not receive instruction on changing lifestyle habits. Outcomes will be assessed at baseline, 8 and 14 months. The primary outcome is cognitive functioning; secondary outcomes will include changes in body weight, diet, cardiovascular, metabolic, and inflammatory biomarkers (26).

Regarding the MeDi role in treating cognitive decline, the group led by Samieri showed that MeDi postpones cognitive aging with 1 year and reduces the risk of MCI and the conversion rate from MCI to dementia. Before that, Feart et al stated that there is a therapeutic window of 5 years before the clinical diagnosis of Alzheimer's disease in which MeDi can be used as a therapeutic strategy with very good effects on the cognitive function (27). The cognitive decline may be also reduced by lowering the cardiovascular risk, mission in which MeDi has already proved efficient, by lowering blood pressure, cholesterol, lipids, body weight and supporting the pharmacological treatment in many metabolic diseases (28).

CONCLUSIONS

In our opinion nutrition plays a decisive role in the maintenance of cognition, thus successful brain aging is an achievable goal for dietary therapies. We reviewed studies that highlight the implication of epigenetic nutritional events in modulating the cognitive abilities and that raises the possibility of dietary manipulations as a viable strategy for treating brain related pathology. In our review evidence is suggestive of a neuroprotective role for the Mediterranean Diet, but variation between studies makes it difficult to draw firm conclusions. Further

investigation is needed to determine whether the MeDi represents an optimal dietary pattern for protection against neurodegeneration in representative populations.

Our conclusion is that higher adherence to Mediterranean Diet is associated with slower cognitive decline and lower risk of developing Alzheimer disease. Long-term randomized controlled trials promoting a Mediterranean Diet and life style may help establish whether improved adherence helps to prevent or delay the onset of Alzheimer disease and other types of dementia. What we are sure and has been proved is that in brain aging and preventing cognition decline a multidomain intervention is required including proper nutrition, supported physical exercise and updated pharmacological treatment.

PREDICTING GESTATIONAL DIABETES MELLITUS THROUGH SERUM SEX HORMONE BINDING GLOBULIN LEVEL

A group of researchers conducted a study that assessed the sex hormone binding globulin(SHBG) as a valuable biochemical marker in predicting gestational diabetes mellitus(GDM). Circulating SHBG levels are inversely associated with insulin resistance. In this case controlled study were included 90 pregnant women, 45 women with GDM and 45 matched controls. They measured the serum SHBG levels by Enzyme-linked immunosorbent assay(ELISA) method between 24 and 28 weeks of gestation. Compared with the control group, SHBG concentrations were significantly lower in the GDM group; 23nmol/L vs. 78 nmol/L. The autors concluded that patients with GDM have lower circulating levels of SHBG than normal glucose tolerance pregnant women, so circulating concentrations of SHBG represent a potentially useful new biomarker for prediction of risk of GDM.(Tawfeek MA, Alfadhli EM, Alayoubi AM, El-Beshbishy HA, Habib FA. Sex hormone binding glubulin as a valuable biochemical marker in predicting gestational diabetes mellitus. *BMC Women's Health* 2017; 17: 18 DOI**:** 10.1186/s12905-017-0373-3)

A NEW REALITY: GUT MICROBIOTA AND INFLAMMATORY SYSTEMIC DISEASES (Abstract): Microbiota refers to the total microorganisms of the microbial community, while the term microbiome refers to a group of microbes that includes bacteria, bacteriophages, fungi, protozoa and viruses. Microbiota is an organ with its own functions that can modulate the expression of genes involved in the defense of mucosal barrier, angiogenesis and postnatal intestinal maturation. Changes in the composition of gut microbiota -dysbiosis- may be associated with nosocomial infections, necrotizing enterocolitis in premature infants, inflammatory bowel disease (IBD), obesity, rheumatologic autoimmune diseases and allergies. Dysbiosis increases intestinal permeability and the microbial translocation through the mucosa, thus resulting inflammation and metabolic endotoxemia. Therefore, are generated many proinflammatory cytokines and oxygen free radicals, all of which are considered triggers for the development of immuno-inflammatory systemic disease. Many clinical studies have examined the link between autoimmune diseases and dysbiosis using 16S rRNA genetic analysis. Clear evidences of association with intestinal dysbiosis have been described in patients diagnosed with IBD, spondylarthropathies, rheumatoid arthritis or systemic lupus erythematosus. **Keywords**: MICROBIOATA, INTESTINAL DYSBIOSIS, INFLAMMATORY BOWEL DISEASE, SPONDYLARTHROPATHIES, RHEUMATOID ARTHRITIS, SYSTEMIC LUPUS ERYTHEMATOSUS.

Bacterial intestinal flora includes about 10^{14} bacteria which represents 10 times more than the number of cells in the human body (1, 2). Since birth, the normal intestinal microbiota contributes to the development of intestinal function, modulates the immune system, helps to regulate and maintain intestinal function, provides protection against infection and tolerance to food intake. We can talk about a symbiosis of the bacteria-host interaction. Intestinal microbiota diversity includes more than 1,500 microbial species, dominant bacteria group being phyla species: *Firmicutes* and *Bacteroidetes*. The phyla group also includes: *Proteobacteria*, *Actinobacteria*, *Fusobacteria* and *Verrucomicrobia* (3).

Microbiota has multiple roles in the development of the intestinal immune system by: the modulation of intestinal mucous layer and lymphoid structures, differentiation of immune cells and immune mediators'

production, positive stimulatory effect on the innate and adaptive immune system (4).

Changes in the composition of gut microbiota - dysbiosis - may be associated with nosocomial infections, necrotizing enterocolitis in premature babies, inflammatory bowel diseases (IBD), obesity, rheumatologic autoimmune diseases and allergies. Dysbiosis increases intestinal permeability and the microbial translocation through the mucosa, thus resulting inflammation and metabolic endotoxemia. Therefore, many proinflammatory cytokines and free radicals are generated (5).

Dysbiosis influence the intestinal mucosa by interacting with epithelial cells and by the enteric nervous system, leading to changes in intestinal motility, sensory function and the perception of pain (6). Also, dysbiosis is associated with the development of gastrointestinal and extra intestinal disorders, as well as with an impaired liver function (5,7).

MICROBIOTA AND INFLAMMATORY BOWEL DISEASE

Genetics and environmental factors and the host immunity forms a triad that it has been shown to regulate the TCR function (Toll like receptor). When this relationship is disturbed, it can develop aberrant TCR signals which contribute to the formation of inflammasomes that will cause intestinal inflammation (8).

Risk factors for the occurrence of IBD include factors that influence the composition of intestinal microbiota - maternal exposure, breastfeeding, diet, antibiotics, infections and factors affecting mucosal immune system - smoking, Nonsteroidal anti-inflammatory drug (NSAIDs), oral contraceptives, vaccination, intestinal permeability, appendectomy, stress (9). A model of colitis on laboratory mice showed that, after the administration of 4 antibiotics for 4 weeks, the deletion of commensal gut microbiota can cause severe intestinal mucosal impairment (10). Extended use of antibiotics is associated with increased risk of Crohn's disease (CD), but not with ulcerative colitis (UC) (11).

One study attempted to investigate the impact of IBD on intestinal microbiota being analyzed 89 sigmoid mucosal biopsies in healthy individuals and in patients with CD and UC who achieved remission. On these biopsy samples 16sDNA and rARN genetic analysis were performed. Results showed an abundance of *Bacteroides* in the control group and in patients with UC, an increase of *Firmicutes* in both IBD, a reduced activity of *Faecalibacteria* in patients with CD, an increase in the prevalence and activity of *Papillibacter* in healthy persons; only *Prevotella* was positively associated with CD (12).

Dysbiosis in CD is characterized by: a greater number of mucosal bacteria compared to healthy individuals, alteration of the balance between beneficial and aggressive bacteria and by the reducing of the phyla diversity group *Firmicutes* and *Bacteroides* (13). Increased prevalence of intracellular pathogens in CD may be due to the innate immune system's inability to control persistent infections caused by intracellular bacteria.

Patients with ileal and colonic CD have a low concentration of commensal bacteria concerning the *Clostridiales* group as *Faecalibacterium prausnitzii* and *Roseburia* (14), these being regarded as predictive marker for postoperative ileal CD (15). An increased number of bacterial species found in CD include *Escherichia coli* especially B2 and D groups and those with adherent / invasive strains associated with a severe ileal disease (16).

MICROBIOTA AND INFLAMMATORY RHEUMATIC DISEASES

Except reactive arthritis in which there are clear evidences that bacterial infections can cause articular manifestations, currently studies show only hypotheses regarding the role of gut microbiota in immune-mediated arthritis. However, a study conducted on mice having ankylosing spondylitis (AS) and positive antigen HLA-B27 and which were maintained in germ-free conditions highlighted that they didn't developed articular inflammation (17).

Recent studies (18) argue that, intestinal dysbiosis in patients with SA correlates with the presence of the antigen HLA-B27. To detect bacteria associated to HLA-B27, 16S rRNA sequencing had been used and elevated populations of *Paraprevotella* and *Bacteroides vulgatus* have been highlighted. Altered intestinal bacterial composition characterized by: increasing populations of *Lachnospiraceae, Ruminococcaceae, Rikenellaceae, Porphyromonadaceae, Bacteroidaceae*, alongside the decreasing of *Veillonellaceae* and *Prevotellaceae* constitutes a risk factor for developing SA (19).

A recently published study (20) supports the important role of intestinal dysbiosis (especially Dialister gender) in spondylarthropathies. There have been included 27 patients of which 14 showed microscopic intestinal inflammation and 13 without gut inflammation. Ileal and colonic biopsies were performed. To compare the intestinal microbial composition 16SrARN sequences were used. The results showed that the microbiota of patients with spondylarthropathies was associated with intestinal inflammation and *Dialister* gender was positively correlated with the ASDAS score (Ankylosing Spondylitis Disease Activity Score).

Other diseases such as rheumatoid arthritis (RA) or systemic lupus erythematosus (SLE) may have as pathogenic mechanism intestinal dysbiosis which contributes to the development of arthritis through activation of autoreactive T cells in the gut (21). Dysbiosis in RA is characterized by a depletion of *Haemophilus spp*. - negatively correlated with the level of autoantibodies - and an increasing of *Lactobacillus salivarius* - especially in cases of very high RA activity (22). Regarding SLE patients, trials evidenced a significant decrease in *Firmicutes* and *Firmicutes/Bacteroidetes* ratio and a significant increase in *Clostridiaceae* and *Lachnospiraceae* groups that correlated with disease progression (23).

MICROBIOTA AND INFLAMMATORY BOWEL DISEASE ASSOCIATED WITH ARTICULAR MANIFESTATIONS

Regarding the association between IBD and rheumatic disorders, namely AS, it must not forget that these conditions have common genetic background and are considered distinct phenotypes of an immune-mediated inflammatory disorder. The strongest genetic association is represented by the antigen HLA-B27.

Intestinal epithelial cells produce mucins and antimicrobial peptides such as lysozyme, defensins and lectins that have a critical role in intestinal homeostasis. Patients with active CD show a marked decrease of DEFA5 and DEFA6 α-defensins, leading to an impaired mucosal commensal microbial flora. Controversially, the studies showed an increased expression of α-defensins in patients with SA having also subclinical ileal inflammation (24, 25).

Regarding IL-17 / IL-22 cytokines relevant to IBD and spondylarthropathies, clear evidences indicate that the interaction between gut microbiota and host causes the activation of immune cells with subsequent production of these types of proinflamma-

tory cytokines (26).

CONCLUSIONS

We can conclude with confidence that the gut microbiota plays an important role in the development of immuno-inflammatory diseases, namely in intestinal and articular disorders. Nevertheless, the specifically pathogenic mechanism remains a challenge for the practitioner physician. The analysis of gut microbiota opens new perspectives in research and for understanding of these systemic diseases.

A NEW BLOOD TEST USEFUL FOR DIFFERENTIAL DIAGNOSIS OF CHRONIC DEGENERATIVE NEUROLOGICAL DISORDERS

Neurofilament light chain protein (NLCP) is a biomarker of degeneration of large myelinated axons. This biomarker is elevated in the cerebrospinal fluid (CSF) in patients with chronic degenerative neurological disorders such as atypical parkinsonian disorders (APD), amyotrophic lateral sclerosis, and frontotemporal dementia but is not increased in Parkinson disease (PD). The use of this biomarker to differentiate between PD and APD is influenced by the patient's decision because lumbar puncture is an invasive maneuver that lowers its compliance and delay treatment decisions. Because prognosis differ dramatically between PD and APD, early differentiation between these diseases is very important. A recent cohort study evaluated the usefulness of NLCP levels determination in the blood in order to differential diagnosis of PD and APD i.e., multiple system atrophy (MSA), progressive supranuclear palsy (PSP), and corticobasal degeneration (CBD), with same accuracy as CSF NLCP. The study included 504 people grouped in three cohorts. Two cohorts included healthy controls and patients with PD, MSA, PSP and CBD with average disease duration of four to six years. The third cohort was comprised of patients with APD with disease duration ≤3 years. The results showed that blood levels of NLCP were elevated in patients with APD compared to healthy individuals and those with PD in all cohorts ($p < 0.001$). Determination of blood levels of NLCP can distinguish between PD and APD, with high diagnostic accuracy (0.81 – 0.91). This accuracy was similar to that obtained when used NLC determination in CSF (0.85–0.90). In researchers' opinion, these findings can improve the diagnostic algorithm of parkinsonian disorders (Hansson O, Janelidze S, Hall S, Magdalinou N, Lees AJ, Andreasson U, Norgren N, Linder J, Forsgren L, Constantinescu R, Zetterberg H, Blennow K. Swedish BioFINDER study. Blood-based NfL: A biomarker for differential diagnosis of parkinsonian disorder. *Neurology*. 2017 Feb 8. pii: 10.1212/WNL.0000000000003680).

A RARE CAUSE OF HIGH INTESTINAL OBSTRUCTION–CASE REPORT (Abstract): Portal vein thrombosis is a frequent thrombotic complication of cirrhosis. Thrombosis can extend to the mesenteric veins, causing acute intestinal ischemia. We report the case of a 61-year-old female who developed high intestinal obstruction caused by distal jejunal infarction one month after an episode of spontaneous bacterial peritonitis. The patient underwent segmental enterectomy with end-to-end anastomosis, with favorable clinical outcome, which allowed us to initiate anticoagulation treatment with low-molecular-weight heparin. Intestinal ischemia due to by mesenteric vein thrombosis can be tardily diagnosed, since it causes nonspecific clinical symptoms. The treatment of mesenteric vein thrombosis requires an interdisciplinary team and includes resection of non-viable intestinal segments, anticoagulation, thrombolysis or trans catheter thrombectomy. However, the use of anticoagulation in cirrhotic patients increases both the risk of esophageal varices rupture and the extent of the bleeding. **Keywords**: PORTAL VEIN THROMBOSIS, CIRRHOSIS, MESENTERIC VEIN THROMBOSIS, INTESTINAL INFARCTION.

Portal vein thrombosis (PVT) is one of the most common thrombotic events in patients with liver cirrhosis (LC). PVT is less common in patients with compensated LC (1%) but has a prevalence of 8-25% in subjects with advanced liver failure, awaiting transplantation (1,2). If in non-cirrhotic patients PVT is often related to prothrombotic states (myeloproliferative neoplasms, inherited coagulation disorders) (3), in cirrhotic subjects the pathophysiology of PVT is more complex. The risk of developing PVT is independently correlated with the severity of the liver damage, since such patients present the three constituents of the Virchow's triad (4, 5). A recent report demonstrated that the activity of von Willebrand factor-cleaving protease is independently correlated with PVT in cirrhotic subjects (6). Modified platelet indices, such as mean platelet volume and platelet distribution width, have been associated with prothrombotic state in cirrhotic patients (7), but a recent study proved that platelet hyperactivity is not correlated with a higher incidence of PVT (8).

While the obstruction of the portal and splenic veins leads to portal hypertension-

related complications, the occlusion of the mesenteric vein is associated with high mortality rates precipitated by intestinal infarction (3, 9). The clinical presentation of intestinal infarction includes persistent abdominal pain, gastrointestinal bleeding, abdominal guarding, contracture and multi-organ dysfunction syndrome (10).

CASE REPORT

ZM, a 61-year-old female, presented at hospital with complaints of vague abdominal pain, nausea, fever and chills. The onset of symptoms was 7 days prior to admission. Her past medical history included LC caused by chronic hepatitis C, for which she had completed the interferon-free therapy in the previous month, with sustained virologic response (SVR).

On admission, she exhibited diffuse abdominal tenderness, tachycardia (110 beats per minute) and normal blood pressure. Routine laboratory tests showed inflammation, slightly elevated creatinine levels, mild thrombocytopenia, anemia and elevated bilirubin levels.

Abdominal ultrasound revealed a small amount of free abdominal fluid (not suitable for paracentesis), enlarged spleen and coarsened liver echotexture. The clinical context, along with the newly developed ascites was suggestive of spontaneous bacterial peritonitis. Antibiotics, antalgics and spasmolytics led to the remission of the symptoms.

The patient was readmitted with nausea and recurrent abdominal pain a month after her initial presentation. On the third day of hospital stay, during the bowel cleansing protocol for colonoscopy, the patient complained of worsening abdominal pain, incoercible vomiting and absence of bowel movements. Laboratory tests revealed worsening renal function and progressive inflammatory syndrome. Abdominal ultrasound detected dilated intestinal loops. Upper endoscopy revealed grade II esophageal varices and gastric distension. Abdominal radiography (X-ray) (fig. 1) showed multiple air-fluid levels in the topography of the small intestine.

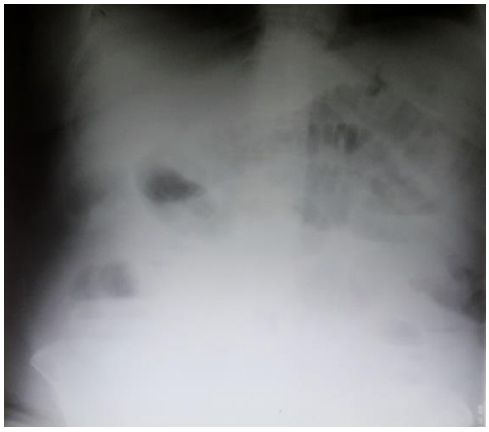

Fig. 1. Plain Abdominal X-ray. Distended intestinal loops, air-fluid levels

Fig. 2. Abdominal CT. The arrow points towards portal vein thrombosis

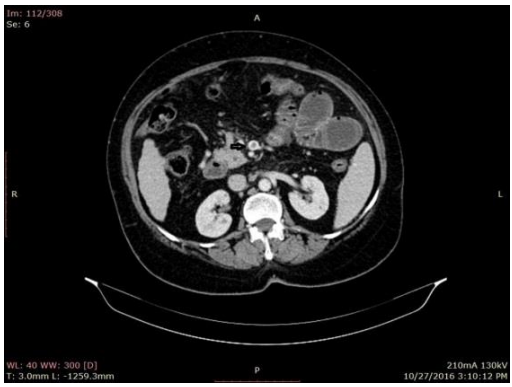

Fig. 3. Abdominal CT. The arrow points towards superior mesenteric vein thrombosis

Fig. 4. Abdominal CT. Bowel wall thickening (up to 12 mm), distended loops

Emergency contrast enhanced computed tomography (CT) described an extensive thrombosis of the portal vein and superior mesenteric vein. The distal part of the jejunum presented radiographic signs of ischemia while the proximal loops appeared dilated and with multiple air-fluid levels (fig. 2, 3, 4). The patient underwent segmental enterectomy (intraoperative aspect-venous jejunal infarction) with end-to-end anastomosis. The clinical outcome was favorable and we initiated low-molecular-weight heparin. Abdominal Doppler ultrasonography performed two months after surgery revealed permeable portal and superior mesenteric vein, with hepatopetal portal flow and no residual venous thrombosis.

DISCUSSION

The development of PVT in a cirrhotic patient is asymptomatic in 43% of cases. However, 39% of patients develop gastrointestinal bleeding and 18% present acute abdominal pain, mostly due to intestinal infarction (5). Diagnosis relies on Doppler ultrasonography. CT and magnetic resonance imaging are indicated to evaluate the extent of the thrombus and to screen for local malignancies (11).

Only 5-15% of cases of intestinal ischemia are attributed to mesenteric venous thrombosis (MVT). MVT is generally associated with malignancies, prothrombotic states, surgery, inflammatory bowel disease, intra-abdominal infections and trauma (12). Infarction due to MVT occurs when the thrombosis fully occludes the venous return. Associated vasospasm, which can persist even after the remission of venous drainage obstruction, has also been reported (13). Venous mesenteric infarction is associated with a mortality rate of 20-60% and frequently requires extended resections, with high risk of postsurgical complications (9).

MVT is rarely localized in the inferior mesenteric vein. The affected bowel segment is usually the ileum (64-83%) and the jejunum (50-80%). The colon is involved only in 14% of cases, due to its numerous collaterals (13).

Subjects usually seek medical care after 5-14 days and the intensity of pain is disproportionate to the clinical exam (13). Our patient presented fluctuating abdominal discomfort, which worsened during bowel cleansing protocol. Fever and signs of peri-

toneal irritation suggest the progression of intestinal infarction (12) but our subject was afebrile during hospitalization. Ascites formation and hypotension are correlated with poor outcome (12).

Laboratory tests are not specific for the diagnosis of MVT and include elevated serum lactate, leukocytosis and hemoconcentration (12). Plain abdominal X-ray is usually negative but this case presented as a high intestinal obstruction, with visible air-fluid levels.

Contrast-enhanced CT is the preferred diagnostic test for MVT. Intestinal ischemia is suggested by wall thickening, bowel distention, modified enhancement patterns, abnormal mesentery and newly developed ascites (13). Although splanchnic angiography is still the gold standard imaging test for MVT, it should be employed only in patients who could undergo intra-arterial treatment. Doppler ultrasound is specific but has low sensitivity as it cannot detect small mesenteric branches (13).

Baveno VI consensus recommends that in patients with acute PVT, non-candidates for liver transplant, anticoagulation with low-molecular-weight heparin or vitamin K antagonists could be considered when the thrombosis extends to the superior mesenteric vein (14). Thrombolysis and trans catheter thrombectomy have proven ineffective in patients with LC. Enterectomy of non-viable bowel segments is recommended (14).

However, early diagnosis of MVT and prompt initiation of anticoagulation can prevent intestinal infarction and the need for surgery. Enterectomy could not be avoided in this case because the patient developed high intestinal obstruction. After the procedure, we considered low-molecular-weight heparin to be the only therapeutically option. Although anticoagulation could increase the risk of esophageal variceal bleeding, we used non-selective beta-blocker for primary prevention of this complication (11, 14). The clinical outcome was positive with complete recanalization of portal and superior mesenteric veins.

Interferon-based therapy for hepatitis C has previously been associated with MVT and ischemic colitis (15), but our patient had undergone the interferon-free regimen. To our knowledge, this is the first published case of acute PVT and MVT after interferon-free treatment in a patient with SVR. Even after viral clearance, advanced hepatic fibrosis and portal hypertension persist and increase the risk of PVT in cirrhotic patients.

CONCLUSIONS

Portal vein thrombosis with extension to the mesenteric vein can complicate the natural course of cirrhosis, independent of viral clearance. The diagnosis of this complication requires a high index of clinical suspicion in cirrhotic patients presenting with new onset ascites and abdominal pain.

NEWS

FATAL FOLIC ACID TOXICITY IN HUMANS

Folic acid is B-9 vitamin. Folic acid is prescribed commonly for pregnant women to prevent neural tube defects in the fetus, patients under chemotherapy, pernicious anemia and to reduce the risk of stroke and cardiovascular disease. Acute or chronic ingestion of a large dose of folic acid generally manifests as neurological complications, which are reversible. A 23-year-old pregnant woman committed suicide by consuming folic acid tablets and succumbed to death within 36 h. Postmortem toxicological analysis detected folic acid in viscera. Death following acute consumption of folic acid is rare and has been not reported in the literature (Devnath GP, Kumaran S, Rajiv R, Shaha KK, Nagaraj A. Fatal Folic Acid Toxicity in Humans *J Forensic Sci.* 2017 Mar 6).

MAGNESIUM IN PEDIATRIC NEPHROTIC SYNDROME (Abstract) **Aim**: In the present study, we aimed to evaluate serum Mg concentration in children with nephrotic syndrome and highlight the relationship between Mg concentration and acute nephropathy. **Material and methods**: We conducted a clinical study in 27 patients, aged 2 to 17 years, admitted to the Nephrology clinic of the Iasi "Sf. Maria" Children′s Hospital between 2011-2015, with the diagnosis of idiopathic nephrotic syndrome (NS), first episode or relapse. In each patient, we investigated serum urea and creatinine, total cholesterol, total serum proteins, serum magnesium, urinary proteins, creatinine clearance and renal histopathology. We also used a control group of 14 children with normal renal function. **Results**: 12 patients had NS in the acute phase, 6 steroid responsive and 6 steroid resistant. The remaining 15 patients were in the remission phase of NS, 7 steroid responsive and 8 steroid resistant. Significantly decreased serum Mg levels were found in NS active group compared to control group. Renal histopathological analysis in steroid responsive patients revealed the following pathological aspects: optically normal glomeruli (1 case), minimal mesangial changes (5 cases), IgM nephropathy (4 cases), mesangioproliferative glomerulonephritis (4 cases). **Conclusions**: The variations of serum and urinary Mg levels in children with acute nephropathy may be useful for early diagnosis and improving therapy. **Keywords:** MAGNESIUM, NEPHROTIC SYNDROME, CHILDREN.

Nephrotic syndrome (NS) is one of the most frequently encountered glomerulopathy in children, being characterized by altered permeability of the glomerular capillaries and the inability to control urinary protein loss, leading to hypoproteinemia, hyperlipidemia and edema (1). Of all NS cases, about 90% are idiopathic, with favorable response to corticosteroids, and good prognosis. Ten percent of cases are steroid resistant, with little or no response to usual corticosteroid treatment (2, 3).

In terms of histopathology, NS can have the following aspects: minimal change disease (76.4%), mesangioproliferative glomerulonephritis (2.3%), membranoproliferative glomerulonephritis (7.5%), focal segmental glomerulosclerosis (6.9%), and membranous nephropathy (1.5%). Of the patients with minimal change disease, 95% respond favorably to corticoids (4). In NS, impaired glomerular function causes tubulointerstitial alterations through different mechanisms: glomerular hemodynamic and

selectivity disturbances, immunologic mechanisms, inflammatory mediators, leukocyte migration. All these lead to destruction of the glomeruli and renal tubules, and finally to tubulointerstitial lesions (5). About one third of steroid-resistant cases evolve towards end stage renal disease within 5 years of disease onset. Histopathology with minimal glomerular damage and mild mesangioproliferative glomerulonephritis has a benign clinical and pathological course without major tubulointerstitial lesions. Instead, focal segmental glomerulosclerosis and diffuse mesangioproliferative glomerulonephritis associate significant tubulointerstitial alterations and an increased risk of developing chronic kidney disease (6). Thus, early recognition of the histopathologic type and of the degree of the tubulointerstitial damage could be useful in establishing a targeted and effective therapy.

In the present study, we aimed to evaluate serum Mg concentration in children with nephrotic syndrome and highlight the relationship between Mg concentration and acute nephropathy.

MATERIAL AND METHODS

We conducted a retrospective study of 27 patients, aged 2 to 17 years, admitted to the Nephrology clinic of the Iasi "Sf. Maria" Children′s Hospital between 2011-2015 with the diagnosis of idiopathic nephrotic syndrome, first episode or relapse. Also, included in the study were patients diagnosed before the year 2011, but who during the study interval had at least one hospitalization for treatment and reassessment. Of the 27 patients, 12 had acute nephrotic syndrome, 6 steroid-responsive and 6 steroid-resistant. The remaining 15 patients were in the remission phase of NS, 7 favorably responding to corticosteroid therapy and 8 being steroid-resistant.

Inclusion criteria were: age 0 - 18 years; diagnosis of idiopathic nephrotic syndrome. Exclusion criteria were: diagnosis of congenital nephrotic syndrome or secondary nephrotic syndrome; simultaneous presence of other diseases such as systemic lupus erythematosus, Henoch-Schonlein purpura, conditions that could cause magnesium loss (gastrointestinal illnesses, burns), administration of nephrotoxic substances (loop diuretics, gentamicin, contrast agents).

The following data were collected from each patient: socio-demographic characteristics, biochemical parameters: urea, creatinine, total cholesterol, total serum proteins, serum magnesium, urinary proteins, creatinine clearance, and renal histopathologic appearance. Measurement of all investigated parameters was performed using the standard methods of biochemistry and histopathology laboratories of the "Sf. Maria" Children's Hospital. Creatinine clearance was calculated using the formula: Cl Creat (ml/min/1,73m^2) = ((0,035 x Age (years)) + 0,236) x 100) / serum creatinine (mg/dL) (7) and renal histopathological analysis.

We used a control group of 14 children, aged 2-17 years, with normal renal function, hospitalized in the General Pediatrics Clinic with functional abdominal pain syndrome, in which we followed-up the serum Mg levels for comparing them with the levels reported in the study group. The study was conducted with the approval of the Ethics Committee of the institution for the use of medical data and informed consent was obtained from all patients. Statistical analysis was performed using unpaired t-test and Fisher's test. The results were expressed as mean ± standard devia-

tion. Coefficient p values <0.05 were considered statistically significant.

RESULTS

The study was conducted on a sample of 27 patients (16 males and 11 females), aged 2 to 17 years, diagnosed with idiopathic nephrotic syndrome, which had at least one hospitalization in the Nephrology Clinic in the interval 2011-2015. The diagnosis of nephrotic syndrome was based on the presence of the following biological changes: hypoproteinemia, hypercholesterolemia, proteinuria. For NS in remission phase, the values of these parameters were within normal ranges.

In the study group, 12 patients had acute NS and 15 patients NS in remission phase. Depending on the response to treatment, steroid resistance was detected in 6 patients with active SN and 8 patients in remission (fig. 1).

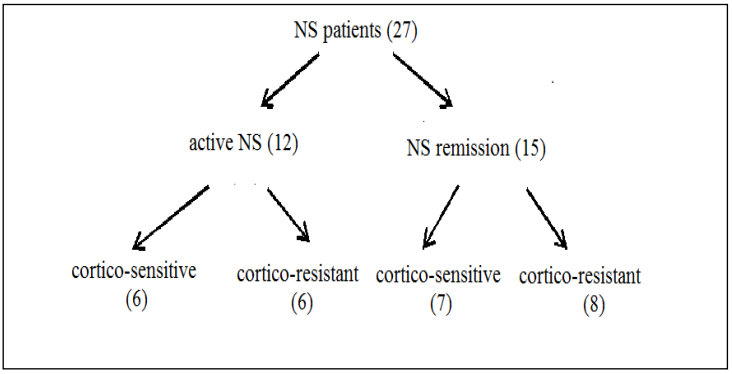

Fig. 1. Distribution of nephrotic syndrome in the study group

The mean age was 6.58 ± 4.14 years for active NS group, and 9.66 ± 4.65 years for remission NS group.

TABLE I

Biochemical parameters in study patients

Parameter	active NS (n=12)	NS remission (n=15)
total serum proteins (g/l)	44.62 ± 7.18*	68.21 ± 5.40
total cholesterol (mg/dl)	381.16 ± 134*	169.06 ± 31.49
urinary proteins (mg/dl)	300 ± 0*	0
urea (mg/dl)	32.91 ± 11.62	27.33 ± 6.14
creatinine (mg/dl)	0.71 ± 0.58	0.59 ± 0.12
creatinine clearance (ml/min/1,73m^2)	82.23 ± 31.38	96.90 ± 23.63
Serum Mg (mg/dl)	1.96 ± 0.30*	2.31 ± 0.77

* p<0.0001

The investigated parameters, namely total serum proteins, total cholesterol and urinary proteins, showed mean levels significantly different in patients with active NS compared to children with NS in remission. Thus, in the active NS group compared to remission NS group, serum proteins levels were low (p<0.0001), serum

total cholesterol levels were higher ($p<0.0001$) and proteinuria was present in all children with active NS, while patients in remission showed no urinary protein loss ($p<0.0001$) (tab. I). All these data confirmed the acute nature of the disease in the active NS group, and the favorable response to treatment with occurrence of remission and normalization of parameters that are typically affected in acute nephropathy for the group with NS in remission. Regarding renal function parameters, serum urea and creatinine, one case of azotemia was reported in active NS group (serum creatinine 2.47 mg/dl), while in NS remission group there was no case of nitrogen retention. Also, creatinine clearance values did not vary significantly between acute NS patients and NS remission group (tab. I).

Renal histopathological analysis of steroid-resistant patients in the 2 groups revealed the following pathological aspects: active NS group: optically normal glomeruli (1 case), minimal mesangial changes (2 cases), IgM nephropathy (3 cases); remission NS group: minimal mesangial changes (3 cases), mesangioproliferative glomerulonephritis (4 cases), IgM nephropathy (1 cases). The most common histological aspect was minimal mesangial changes (36%), followed by the mesangioproliferative aspects (29%) and IgM deposits (28%).

TABLE II.

Serum Mg (mg/dl) in the groups active NS, remission NS and control. Statistical significance – unpaired t test

Group	n	Mean	Standard Deviation	Standard Error	Min	Max	p
Active NS	12	1.96	0.30	0.08	1.53	2.30	<0.05*
Remission NS	15	2.31	0.77	0.19	1.61	4.81	0,71
Control	14	2.23	0.10	0.02	2.10	2.43	

*vs. control

The results showed decreased serum Mg levels in active NS group (1.96 ± 0.30 mg/dl) compared to control group (2.23 ± 0.10 mg/dl), the difference being statistically significant ($p<0.05$) (tab. II). However, although serum Mg was significantly lower in patients with acute nephropathy compared to controls ($p<0.05$), divalent cation concentration showed no significant variation between active and remission groups.

DISCUSSION

Literature data (8, 9) have suggested a link between serum and urinary Mg and tubulointerstitial function, given that both reabsorption of filtered Mg and retention of serum Mg occur in renal tubules. Any structural or functional alteration of the renal epithelium interferes with the tubular loss and reabsorption of Mg, leading to increased Mg urinary excretion. Hypomagnesemia is a common electrolyte disorder which occurs in approximately 12% of hospitalized patients. This incidence may increase to 60-65% in patients in Intensive Care Units due to nutritional deficiencies, hypoalbuminemia, hypotension, sepsis, use of such medications as diuretics or amino-

glycosides (10).

The results of our study show that serum Mg levels were significantly lower in patients with active nephropathy compared to those in remission ($p<0.5$). Since Mg is a divalent cation and its homeostasis depends on kidney filtration, low Mg levels in children with active NS reflect an alteration of renal excretion and reabsorption of Mg (11, 12).

In the literature, there are few studies regarding the implications of Mg deficiency on renal function after an episode of acute kidney injury (AKI). Santos et al. (13) showed that hypomagnesemia is a risk factor for irreversible renal function recovery in patients with AIDS (acquired immunodeficiency syndrome) and AKI. Similarly, Alves et al. (14) investigated Mg variation in a group of 232 patients admitted in the Intensive Care Unit and who experienced impaired renal function. It has been demonstrated that the prevalence of hypomagnesemia was 63% in the study group, the patients who showed no recovery of renal function having a significantly higher prevalence of hypomagnesemia (70%) compared with those with recovered renal function (31%).

Cheungpasitporn et al. (15) investigated the link between Mg variation and the occurrence of renal impairment in a group of 9241 patients, of which 124 developed AKI. Their results showed that the lowest incidence of AKI was in patients with serum Mg levels within the normal range, between 1.7 and 2.1 mg/dl. Instead, both hypomagnesemia (< 1.5 mg/dl) and hypermagnesemia (> 2.3 mg/dl) were associated with a higher incidence of developing kidney damage.

There are several theories that may explain the association between magnesium deficiency and renal impairment in AKI. Mg competes with calcium (Ca) transport in the cell membranes, leading to decreased intracellular calcium concentration, and secondary to smooth muscle relaxation (16). Administration of Mg produces peripheral vasodilatation, predominantly arteriolar, not only by stimulating the production of nitric oxide, but also by its ability to antagonize directly with Ca (17).

In addition to vasodilatory effects, Mg is associated with effects on microcirculation, such as: increased deformability of red blood cells, reduced platelet aggregation, anti-inflammatory effects, maintaining the endothelial integrity (18). Other similar studies (8, 19) which have investigated the homeostasis of Mg in nephrotic syndrome, showed the existence of increased Mg urinary excretion, in focal and segmental glomerulosclerosis and mesangioproliferative glomerulonephritis. Also, Gheissari et al. (20) revealed elevated renal Mg excretion, suggesting the possible use of Mg concentration as an early marker for detecting the tubular malfunction and as an indicator of residual tubular lesions.

Our results showed, in patients with steroid resistant NS, histopathological lesions which are consistent with literature data, indicating the presence of minimal change glomerulonephritis in steroid resistant NS in proportions ranging from 25% (21) to 45.5% (4).

CONCLUSIONS

The present clinical trial is particularly useful in medical practice, suggesting the importance of investigating the variations of serum and urinary Mg in pediatric acute nephropathy, along with standard measures of other ions such as Na, K, Cl, with the possible early detection of patients with unfavorable response to therapy.

ADVANCED SARCOIDOSIS WITH APPARENT ONSET BY RESPIRATORY FAILURE (Abstract). We present the case of a 14 years-old male (with poor living condition, non-smoker) hospitalized for a sudden onset of a rest dyspnea, mucopurulent cough. We found bronchial sibilant rales, wheezing, cyanosis, peripheral adenopathies, hepatosplenomegaly, purulent tonsilitis. The chest-x-ray revealed bilateral mediastinal lymphadenopathy and bilateral lung infiltrations. Spirometry: severe mixed ventilatory dysfunction without reversibility. Sputum: negative microscopy and culture for Koch bacillus. Stool examination: cysts of Lamblia giardia. The patient refused bronchoscopy and mediastinoscopy, so it was performed axillary lymph node biopsy which confirmed sarcoidosis (non-caseating epithelioid granulomas). The treatment included antibiotics, antiparasites, oral and inhaled corticosteroids (CS), bronchodilators, oxygen, with clinical/functional improvement after 3 months. CS was followed 1.5 years with poor compliance. A relapse occurred after 3 years and the CS were reinserted. The computerized tomography (CT) scan revealed a diffuse interstitial fibrosis with bronchiectasis. The case particularity relies on the atypical early onset of the sarcoidosis, with respiratory failure and progression to lung fibrosis despite CS treatment. The association of proinflammatory risk factors such as multiple infections needs to be noted.
Keywords: SARCOIDOSIS, LUNG FIBROSIS, RESPIRATORY FAILURE

Sarcoidosis (S) is a multiple organ granulomatous disorder of unknown etiology. It usually affects young and middle aged adults and initially involves target organs – lung, lymph nodes, skin, eye, joint and liver but it can overtake all organ systems. Organ like salivary glands, heart, nervous system, muscles, bones, kidney are also frequently affected in extra pulmonary S (1). The S diagnosis is established upon clinical and radiological aspects supported by the histopathological evidence of the noncaseating epithelioid granulomas. Commonly seen immunological aspects are depression of the delayed cellular immune response and B lymphocytes over response (1, 2). The treatment depends upon staging, locations, respiratory functional tests (RFTs) and symptoms. For stage II or III pulmonary sarcoidosis (PS) and impaired

RFTs, oral steroids (OS) are recommended. The proper length of therapy for patients who respond to treatment is unknown (6 months - 1 year) (3). Every 3 months, clinical features, chest-x-ray and RFTs will be monitored. Angiotensin-converting enzyme activity (ACE) seems to be sensitive for the diagnosis and evolution assessment and the OS therapy monitoring (4).

CASE REPORT

A 14-year-old male (with poor living condition, from rural area, non-smoker) was admitted in the Pulmonology Clinic with an apparently acute onset of a rest dyspnea, high fever, asthenia, weight loss (7 kg/2 weeks), nasal obstruction, productive cough. The patient's medical history noticed frequent adenoiditis and repeated acquired pneumonia. We found cyanosis, axillaries enlarged lymph nodes, diffuse bilateral sibilants, hepatosplenomegaly, purulent tonsillitis. The chest-x-ray revealed bilateral mediastinal/hilar adenopathies, diffuse interstitial opacities and bilateral basal infiltrative condensation (fig.1). Spirometry: severe mixed ventilator dysfunction (the Vital Capacity - VC 50%, Forced Expiratory Volume in one second - FEV1 52%) and oxygen saturation: 90% in ambient air.

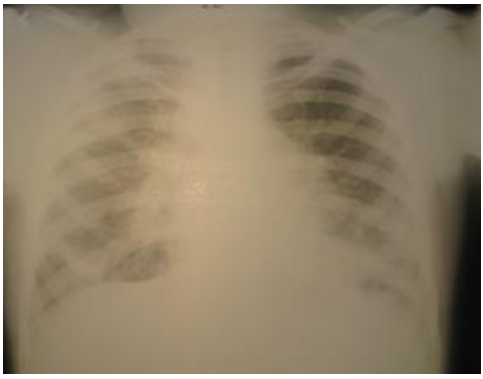

Fig. 1. Chest radiograph: stage II sarcoidosis

The blood tests: leukocytosis 21.000/µL with neutrophilia, increased hepatic enzymes (57.103 U/L), mild anemia, dysproteinemia (α2 - 16%; β - 21%; γ - 26,7%; albumins - 29%) and pathological antibodies: IgG - 1100mg%; ASLO - 600 UI. Blood cultures and tuberculin skin tests were negative and Koch bacilli were negative in sputum (microscopy and culture). Pharyngeal exudate reveals 2 germs: *Staphylococcus aureus* and *Streptococcus beta-hemolyticus*. Stool examination: cysts of *Giardia lamblia.* The patient refused the mediastinoscopy and bronchoscopy however the axillaries lymph node biopsy confirmed the S by highlighting of non-caseating epithelioid granulomas.

The final diagnostic was: evolutive stage II pulmonary sarcoidosis with extra pulmonary lymph nodes and liver/spleen involvement; bronchopneumonia; severe mixed ventilatory disorder and respiratory failure; digestive lambliasis.

A complex treatment was started: oxygen therapy, oral corticosteroids (OCS) 0.7 mg/kg (initially for 3 months, then with gradually decrease with 10 mg/month till 20 mg/kg). The patient had 10 days with antibiotics, antiparasitic treatment, inhaled corticoids and long term bronchodilators. Clinical status improved slowly and the patient was discharged after 14 days with OCS. After 2 months we noticed a favorable evolution with weight gain, return in appetite and RFTs improvement with 33%. The OCS lasted 1.5 years but the patient had a modest compliance to medical controls and treatment.

A relapse of the disease occurs after 3 years. RFTs dropped toward a very severe ventilatory disorder (VC 39%, FEV1 42%) and ACE raised to 120 U/l announcing an evolutive phase of S. The computerized

tomography (CT) scan revealed a diffuse interstitial fibrosis with bronchiectasis and right upper honeycomb image (fig. 2, 3).

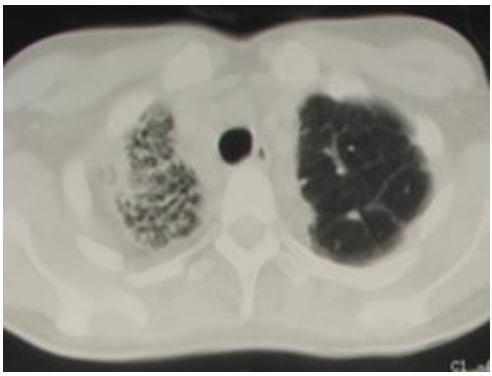

Fig. 2. Thoracic CT: stage III/IV sarcoidosis with extended fibrosis and bronchiectasis in the right upper lobe and emphysema in the left upper lobe

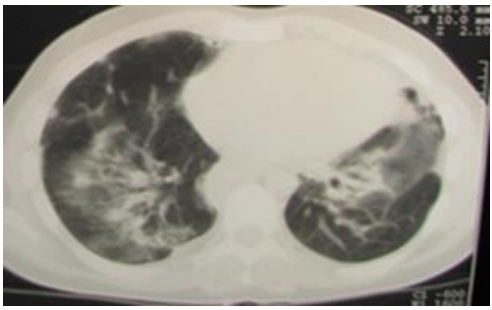

Fig. 3. Thoracic CT: stage III/IV sarcoidosis with diffuse interstitial fibrosis and bronchiectasis

We reinserted OCS, inhaled corticoids/bronchodilators and antibiotics in short cure. We also recommended dental medicine treatment and respiratory rehabilitation. 1-year treatment was conducted with favorable outcome. The patient's reassessment was difficult because of the lack of cooperation to medical investigation and controls. The patient is now in a stable condition but with advanced ventilatory mixed disorder (VC 45%, FEV1 48%). He is following combined inhaled corticoids/bronchodilators.

DISCUSSION

Sarcoidosis can occur at any age but it is relatively rare for children. Our case had an apparently acute onset at the age of 14, but in reality the patient was already in the second stage of the disease with extra pulmonary involvement and a previous slow onset. It was found that an acute onset with erythema nodosum and bilateral hilar lymphadenopathy usually denotes a self-limiting development, while the insidious onset and extra pulmonary lesions predict an evolution toward progressive lung fibrosis (5).

Our patient had cumulated several known risk factors which rushed the disease progression: late diagnosis in a secondary stage of S, with respiratory insufficiency, coexistence of repeated bacterial infection and parasites which made a pressing on immunological host response (1, 6).

We used ACE as a biologic marker to help diagnosis and disease evolution monitoring. It is recognized that elevations greater than two times the upper limits of normal are frequently met in S and much less common in other diseases (tuberculosis, hypertiroidism, Gaucher's disease, lymphoma) (1).

The need for differential diagnostic with lymphoma and tuberculosis was strong and this shows the diagnostic difficulties of the disease, settled here by the histological typical aspect in the axillaries lymph node biopsy. The repeated respiratory infections and parasites may contribute to inflammation, to trigger the disease and its evolution (7).

The inhaled corticosteroids (CS) had a

good tolerance even though he presented bronchial obstruction and diffuse interstitial peri bronchiolar lesions. Several studies have demonstrated some benefit of CS inhaled therapy (8, 9).

CONCLUSIONS

Our case is a useful opportunity for clinical remarks firstly given for the atypical onset - early in the puberty, in an acute presentation with respiratory failure (determined both by the diffuse sarcoid infiltrations and by the over imposed bacterial bronchopneumonia).

We can also note the lack of common symptoms (Löfgren syndrome) and the first presentation in an advanced stage of sarcoidosis (stage II), with extra pulmonary determinations and the rapid evolution towards diffuse interstitial fibrosis despite the corticoid treatment. The patient's lack of compliance to investigations and treatment with frequent OCS abandonment may also contribute to the rapid progression.

CORTICOSTEROID TREATMENT IN THE SETTING OF DECOMPENSATED LIVER CIRRHOSIS WITH RELATIVE ADRENAL INSUFFICIENCY: A CASE REPORT AND A BRIEF REVIEW OF THE LITERATURE

CORTICOSTEROID TREATMENT IN THE SETTING OF DECOMPENSATED LIVER CIRRHOSIS WITH RELATIVE ADRENAL INSUFFICIENCY: A CASE REPORT AND A BRIEF REVIEW OF THE LITERATURE (Abstract): Relative adrenal insufficiency (RAI) is the term used to describe inadequate production or action of glucocorticoids with respect to the severity of the illness. RAI is frequently found in critically ill patients particularly with septic complications and it is also present in both critically ill and stable patients with liver cirrhosis. In the following study a case report of a patient with decompensated cirrhosis and RAI is presented followed by a brief review of the literature. A 65-year-old male with liver cirrhosis of alcoholic etiology was admitted to hospital with bilateral leg edema, ascites, and marked weakness. At admission, his blood pressure was 82/52 mmHg and he had sinus tachycardia of 130/min. Laboratory analysis revealed hyponatremia (122 mmol/L), while ascites fluid analysis showed no infection. During the first 48 hours of hospitalization the patient remained persistently hypotensive despite adequate vascular filling and the addition of noradrenaline. A standard-dose short synacthen test was performed which revealed a poor cortisol response, which is a compatible criterion for the diagnosis of RAI. Intravenous hydrocortisone therapy was initiated, which resulted in a rapid improvement in patient's general condition, and increase in blood pressure. As the patient became hemodynamically stable without the need of noradrenaline, the hydrocortisone dose was weaned progressively, and he was discharged after 18 days of hospitalization in a stable condition. **Keywords:** RELATIVE ADRENAL INSUFFICIENCY; LIVER CIRRHOSIS; HEPATO-ADRENAL SYNDROME; CORTISOL.

Relative adrenal insufficiency (RAI) is the term given to inadequate production or action of glucocorticoids with respect to the severity of illness, and it is frequent in critically ill septic patients (1) as well as in both stable and decompensated cirrhosis with or without sepsis (2-5). The term "hepato-adrenal syndrome" defines an adrenal dysfunction in critically ill cirrhotic patients, and suggests that adrenocortical insufficiency may be a feature of liver disease *per se*, with a different pathogenesis from that occurring in septic shock (4). Only a few studies assessed corticosteroid therapy in critically ill cirrhotic patients with RAI (4,6-8), and the results were

mostly controversial. Some studies reported favorable effects (4,6,7), while a randomized control study (8) has shown no benefit. In this paper, we report a case of a patient with decompensated cirrhosis and RAI, with a brief review of the literature.

CASE REPORT

A 65-year old male with decompensated liver cirrhosis of alcoholic etiology was referred to our hospital with large ascites (grade 3), bilateral leg edema and marked weakness. He had a long history (25 years) of alcohol abuse, although he denied any alcohol intake during the last year. On examination, the patient presented cutaneous arterial "spider" angiomas, palmar erythema, Dupuytren's contractures, grade 3 ascites, peripheral edema, gynecomastia, parotid enlargement, peripheral muscle wasting, mild jaundice, hepatomegaly and splenomegaly. His blood pressure was 78/48 mmHg, he had sinus tachycardia (130/min), and an increased respiratory rate (22/min). The digital rectal examination was normal. Laboratory analysis at admission revealed mild macrocytic anemia, leukocytosis with mild eosinophilia, and thrombocytopenia, elevations of AST, ALT and GGT, hyperbilirubinemia, hypocholesterolemia with low HDL- and LDL-cholesterol values, prolonged INR, hypoalbuminemia, electrolyte disturbance (sodium 122 mmol/L, potassium 2.9 mmol/L). The urine culture was negative and a chest X-ray showed no pathological elements. Abdominal ultrasound showed hepatomegaly with cirrhotic characteristics (nodular structure, heterogeneous echotexture, irregular margins), and signs of portal hypertension (enlarged portal vein of 14 mm, slow portal venous flow, enlarged splenic vein of 11mm, grade 1 splenomegaly) as well as grade 3 ascites. Large-volume paracentesis was performed associated with albumin infusion (8g for every liter of ascitic fluid removed). Ascites fluid analysis showed no infection (< 75 polymorphonuclear cells/mmc). Upper gastrointestinal endoscopy found large esophageal varices. During the first 24 hours of hospitalization, his blood pressure remained low despite vascular filling, and the patient was referred to the intensive care unit where intravenous norepinephrine was added to fluid replacement therapy. However, the blood pressure remained low (80/50 mm Hg), the patient's general condition deteriorated and he complained of marked muscle weakness and fatigue; consequently, an adrenocortical insufficiency was suspected and in the third day of hospitalization a standard-dose short synacthen test (SD-SST) was performed which showed a poor cortisol response, compatible with the criteria of RAI (baseline serum total cortisol < 15 μg/dL, delta cortisol < 9 μg/dL). Thus, in our patient serum total cortisol levels at baseline and 60 minutes after the corticotropin stimulation were 9.6 and 12.5 μg/dL, respectively, with a delta cortisol value of 2.9 μg/dL.

The patient received hydrocortisone intravenously 50 mg every 6 hours, beginning with the third day of hospitalization, and the blood pressure values as well as the patient's general condition greatly improved during the following 24 hours. The norepinephrine dose was gradually reduced and in the fifth day of hospitalization the vasoactive treatment was stopped with no significant change on the blood pressure. The hydrocortisone was weaned progressively (50 mg/day) and the patient was discharged after 18 days of hospitalization

in stable condition on spironolactone and propranolol.

DISCUSSION

Over the last two decades, several studies have reported that in critically ill patients with sepsis the adrenal glands respond inappropriately to stimulation, a condition named initially "relative adrenal insufficiency" (RAI). The name was replaced more recently by the term "critical illness related corticosteroid insufficiency" (CIRCI), defined as an "inadequate cellular corticosteroid activity for the severity of the patient's illness" (9). Both cirrhosis and septic shock share many hemodynamic abnormalities (e.g. hyperdynamic circulatory failure, peripheral vasodilatation, low blood pressure, increased production of proinflammatory cytokines) (10,11) and, consequently, several studies reported that RAI was found in critically ill cirrhotics with or without sepsis (2-4,6,7,12), in patients with stable cirrhosis (3,5,13), and in liver transplant recipients (4,14). The term "hepatoadrenal syndrome", used for the first time by Marik et al (4) defines adrenal insufficiency in critically ill advanced liver disease with sepsis and/or other complications, suggesting that adrenocortical insufficiency may be a feature of liver disease *per se*, with a different pathogenesis from that occurring in septic shock.

Mechanisms of RAI in cirrhotic patients remain largely unknown; however, they may include endotoxemia, impaired synthesis in total cholesterol, HDL and LDL, increased levels of proinflammatory cytokines, and "exhaustion" of the adrenal cortex due to the low levels of steroidogenic substrate (total cholesterol, HDL, LDL) (15).

The diagnosis of RAI in cirrhotic patients is based on the laboratory tests. SD-SST measures total serum cortisol at baseline and 60 minutes after intravenous or intramuscular injection of 250 μg of synthetic ACTH [tetracosactrin (synacthen Novartis Pharma AG, Basel, Switzerland) or cosyntropin (cortrosyn, Amphastar Pharmaceuticals, Rancho Cucamonga,CA, United States)]. A basal serum total cortisol level < 5 μg/dL indicates RAI, while a level > 15 μg/dL will rule out RAI (11). In critically ill patients with cirrhosis RAI is defined either by basal serum total cortisol < 15 μg/dL (2,6) or a delta cortisol (difference between basal serum total cortisol and serum total cortisol after stimulation) < 9 μg/dL (2,6,8,12). Other studies used a peak cortisol level (highest serum total cortisol concentration after stimulation) < 18 μg/dL (7) for the definition of RAI. Most of the studies that included critically ill cirrhotic patients used SD-SST for the diagnosis of RAI (2,6,7,12), while only a few performed a low dose-short synacthen test (LD-SST) (3,4) which uses 1 μg of synacthen given intravenously and serum cortisol measured after 30 minutes. Due to the limitations of all available diagnostic tests, SD-SST remains the most used test for the diagnosis of RAI in critically ill cirrhotic patients, while LD-SST seems to be more appropriate in non-critically ill patients with cirrhosis (11).

The data on corticosteroid therapy in critically ill cirrhotic patients and RAI is controversial, some studies reporting favorable results (4,6,7), while others showing no benefits (8). Harry et al (7) retrospectively assessed the effect of hydrocortisone treatment in a case-control study involving two groups of cirrhotic patients with hemodynamic instability and vasoactive treatment. The group that received hydrocortisone treatment (300 mg/daily)

had a decrease in noradrenaline requirement, but no benefit in survival. Marik et al (4) evaluated the effect of hydrocortisone given intravenously (300 mg/daily) in a group of cirrhotic patients with hemodynamic instability and found that in patients with RAI hydrocortisone therapy was associated with a significantly lower mortality rate and with a significant reduction of the norepinephrine dosage compared with those patients without RAI. Fernandez et al (6) using SD-SST, reported RAI in 17 of 25 cirrhotics with septic shock, and found that patients who received hydrocortisone therapy had higher rates of shock resolution and hospital survival. In a randomized controlled trial, Arabi et al (8) reported that hydrocortisone therapy (50 mg intravenously every six hours until shock resolution) in cirrhotic patients with septic shock was associated with higher rates of shock reversal and significant reduction in vasopressor doses; however, such therapy did not reduce hospital mortality and had higher frequency of shock relapse and gastrointestinal bleeding.

CONCLUSIONS

We presented a case of a cirrhotic patient in which RAI was associated with hemodynamic instability and hyponatremia. In our case, treatment with corticosteroids was beneficial and allowed reduction of vasopressor dosage. We therefore conclude that RAI should be suspected and SD-SST performed in any patient with decompensated cirrhosis, hypotension refractory to vasopressors and fluid resuscitation, marked muscle weakness and fatigue, hyponatremia and eosinophilia. Once the diagnosis of RAI is established, treatment with intravenous glucocorticoids can be considered for hemodynamically unstable cirrhotic patients with adrenal insufficiency as it is associated with reduction of vasopressor dosage and may improve survival.

TEA DRINKING AND TUBERCULOSIS

Numerous studies showed that tea drinking helps to prevent obesity, cardiovascular diseases, autoimmune diseases, neurodegenerative diseases and tumors. Chinese researchers discovered the negative association between tea drinking and tuberculosis (TB). Tea leaves contain epigallocatechin-3-gallate, a flavonoid which inhibit the bacterial growth and the bacillus survival in macrophages. The increasing tea consumption is associated with a decreased risk of TB. Subjects who consumed 151-300 g tea / month had a lower risk to develop TB than those with a lower intake of tea. The green tea led to the most evident protection against TB, compared to oolong and black tea. Future studies are needed to determine whether drinking tea can be used in the prevention and control of TB (Mengshi Chen; Jing Deng; Wufei Li; Dan Lin; Congxu Su; Mian Wang; Xun Li; Benjamin Kwaku Abuaku; Hongzhuan Tan; Shi Wu Wen. Impact of tea drinking upon tuberculosis: a neglected issue. *BMC Public Health* 2015;15(515)).

CORRELATIONS BETWEEN ARTERIAL HYPERTENSION INDUCED BY ANGIOTENSIN II AND SYSTEMIC INFLAMMATION IN RAT (Abstract): Angiotensin II has particularly shown to play a key role in the regulation of inflammatory processes in hypertension. **Aim:** The present study aims to correlate the angiotensin II – induced hypertension with systemic inflammation. **Material and methods:** We conducted an experimental study on Wistar male rats who received Ang II via subcutaneous miniosmotic pumps for 2 weeks. Rats were exposed to a 12h light /12h dark cycle. Sham rats were used as control. Systolic blood pressure measurements and a flow cytometric analysis of lymphocyte surface markers were performed. After 14 days, the animals were euthanized under anesthesia with xylazine/ketamine. **Results:** Systolic BP progressively and significantly increased in rats with Ang II chronic infusion. We observed a statistical significant difference ($p = 0.00001$), in terms of T lymphocytes percentage between control rats plasma and Ang II treated rats plasma, in 14 days. **Conclusions:** Angiotensin II is an important mediator of hypertension and directly promotes inflammation by noticeably increasing the quantity of T cells in kidney tissue. **Keywords:** ANGIOTENSIN II, HYPERTENSION, INFLAMMATION.

Hypertension is prevalent in 25% of the adult population and contributes to the development of coronary heart disease, stroke and chronic kidney disease (1). In 2003, the World Health Organization - International Society of Hypertension (WHO-ISH) provided a definition of hypertension as arterial pressure measurements of 140/90 mm Hg or greater (2). In only 5%-10% of patients, the causes of high blood pressure are identified. For the rest of cases the etiology remains unknown, and the hypertension is defined as "essential".

Numerous studies showed that renin angiotensin aldosteron system (RAAS) contributes to cardiovascular and renal homeostasis by generating angiotensin peptides, mainly angiotensin II (Ang II). It has been shown that increased levels of Ang II cause hypertension, cardiovascular hypertrophy (1), increased vascular reactivity to different vasoconstrictor agents (1,3), inflammation (4) and endothelial dysfunction (5). Ang II causes a mild increase in blood pressure having as results T cell activation and inflammation, these factors having as result a

sustained hypertension (6). The present study intends to highlight some correlations between arterial hypertension induced by angiotensin II and systemic inflammation.

MATERIAL AND METHODS

Male Wistar rats (250–260 g) (n=9) received Ang II (300ng/kgc/min) in NaCl 0.9% via subcutaneous miniosmotic pumps, for 2 weeks as previously reported (7). Rats were exposed to a 12h light /12h dark cycle. Sham rats were used as controls (n=9). Care, use, and treatment of all animals in this study were in strict agreement with the guidelines of the animal care from the University of Medicine and Pharmacy "Grigore.T. Popa" Iasi. Basal systolic blood pressure (SBP) measurements were performed for every rat by tail-cuff plethysmography, twice/week at a basal period. After 14 days the animals were euthanized under anesthesia with xylazine/ketamine and we collected blood samples. Flow cytometric analysis was used to study lymphocyte surface markers. Comparisons within groups were performed using paired Student´s t-test.

RESULTS

Systolic blood pressure. Before the treatments, systolic blood pressure was comparable in the two groups (~120 mmHg). Though, systolic BP gradually and significantly increased in animals with Ang II chronic infusion (208±2 mmHg for Ang II versus 120±5mmHg for control group, in the 14th day).

Cellular viability in plasma. In the Ang II treated rats plasma we observed a statistical significant increasing number of PI-positive cells (non-viable) compared to cells derived from control rat plasma (fig. 1).

The cellular viability in plasma from control rats, respectively Ang II treated rats, is shown in fig. 2 and 3.

T and B lymphocytes into plasma. In figures 4 and 5 we revealed the presence of T and B lymphocytes in rat plasma (control lot vs. Ang II lot). We observed a statistical significant difference ($p = 0.00001$), in terms of T lymphocytes percentage between control rats plasma and Ang II treated rats plasma, for 14 days (fig. 6). As shown in figure 7, the percentage of B lymphocytes plasma, was stastistically significant higher on rats treated with Ang II for 14 days ($p<<<0.05$) compared to control lot.

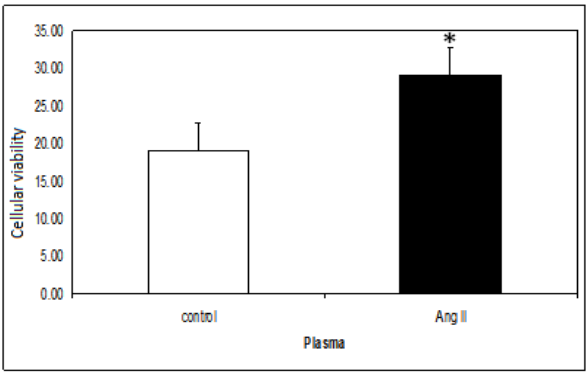

Fig. 1. Cellular viability percentage in rats plasma (control; Ang II) (*p=0.002)

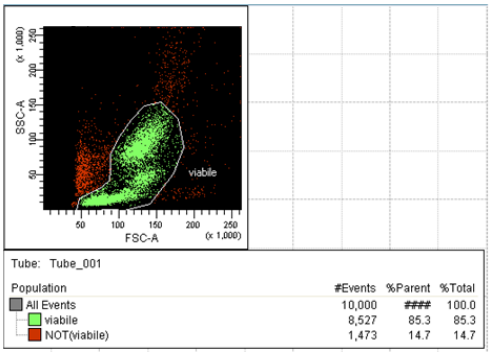

Fig. 2. Cellular viability in plasma (control lot)

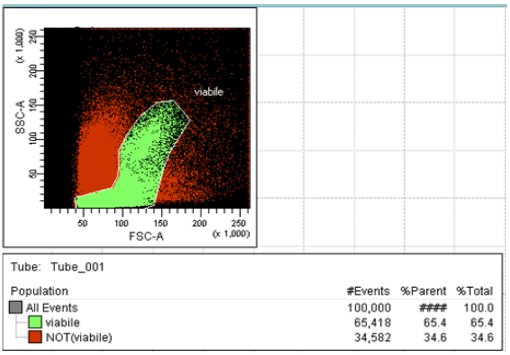

Fig. 3. Cellular viability in plasma (Ang II lot)

T and B lymphocytes into plasma. In figures 4 and 5 we revealed the presence of T and B lymphocytes in rat plasma (control lot vs. Ang II lot). We observed a statistical significant difference ($p = 0.00001$), in terms of T lymphocytes percentage between control rats plasma and Ang II treated rats plasma, for 14 days (fig. 6). As shown in figure 7, the percentage of B lymphocytes plasma, was stastistically significant higher on rats treated with Ang II for 14 days ($p<<<0.05$) compared to control lot.

DISCUSSION

Hypertension should be considered as a potential multifactorial inflammatory disease. Morphological abnormalities in the renal parenchyma and arteries seem to determine hypertension. Inflammatory processes might induce renal vasoconstriction, ischemia and injury that could sustain systemic hypertension. Arterial and tubulointerstitial inflammatory cells infiltration in response to renal damage might further increase renal and vascular alterations through the production of oxidants and other soluble inflammatory mediators (7,8). Increased levels of blood pressure may induce proinflammatory and procoagulant responses.

Up-regulation of local and systemic inflammatory mediators, such as components of the renin-angiotensin system (RAS), endothelial adhesion molecules, chemokines, cytokines and tissue factor (TF), was demonstrated in essential hypertension (9,10,11). The renin angiotensin aldosteron system (RAAS) contributes to cardiovascular and renal homeostasis by generating angiotensin peptides, mainly angiotensin II (Ang II). The effector of the RAAS, angiotensin II, was known mainly as a humoral factor formed by the action of kidney-derived rate limiting enzyme *renin* (12).

Angiotensin II directly modulates cytokine release (13), endothelial adhesion molecule expression and the production of plasminogen activator inhibitor-1 (PAI-1) (14), thus favoring inflammatory vascular and renal damage (15, 16). These studies indicate that angiotensin II, in addition to its well-known cardiovascular effects, could also favor leukocyte recruitment within renal parenchyma in essential hypertension.

The flow cytometry results of the present study comparing control and Ang II treated animals noted that there is a statistically significant difference (p = 0.00001) in the percentage of T lymphocytes in plasma derived from control group rats compared to the percentage of T lymphocytes derived from the plasma of Ang II treated group for 14 days. Also, the percentage of B cells was significantly higher in plasma of rats that were treated with Ang II for 14 days (p <<< 0.05) compared to the percentage of B cells derived from the plasma of controls, confirming hypotheses from the literature regarding the involvement of angiotensin II in the development of inflammatory reactions.

CONCLUSIONS

Our paper reports that T cells play an essential role in the genesis of hypertension and support the involvement of inflammation in the occurrence of this disease. In our study, angiotensin II increased T cell markers activation. Angiotensin II markedly increased the number of T cells in plasma. Thus T cells might represent a novel therapeutic target for the treatment of high blood pressure.

RELATIONSHIP OF CAFFEINE WITH ADIPONECTIN AND BLOOD SUGAR LEVELS IN SUBJECTS WITH AND WITHOUT DIABETES

Insulin resistance or abnormal insulin secretion, are the characteristics of type2 diabetes mellitus (DM2), resulting in a diminished body glucose disposal. Those with chronic hyperglycemia, insulin resistance, or DM2 are at greater threat for its associated risk factors like hypertension, dyslipidemia, and cardiovascular disease. Genetic background and diet are considered to be one of the risk factors for developing type2 diabetes. Interestingly, among the several factors present in diet, coffee is considered as a potent dietary-component associated with reduced risk of diabetes and its complications. Most generally consumed beverage is coffee in the world, and its beneficial effects on health have been attracting substantial consideration. The common protective effect of coffee against diseases like cancer, cardiovascular diseases and type 2diabetes mellitus has been considered. Better glucose tolerance and a substantially lower risk of type 2 diabetes have been connected with high coffee consumption in diverse populations. The components responsible for the obvious beneficial effect of coffee on glucose metabolism remains blurred. Animal studies have shown that intake of the coffee components like chlorogenic acid, quinic acid and trigonelline, has enhanced glucose metabolism. Intervening metabolic studies on short term in humans have shown that caffeine can intensely lower insulin sensitivity. However, a regular high caffeine intake on long term has been linked with improved insulin sensitivity. An important secretory product of adipocytes is adiponectin, a marker and perhaps a mediator of metabolic and cardiovascular disease risk acts as a hormone with anti-inflammatory and insulin sensitizing properties. Further adiponectin levels are low in insulin-resistant subjects regardless of their obesity. A growing body of evidence has shown that high adiponectin levels confirm a protective effect against glucose intolerance budding in patients who are at high risk for diabetes. Further, it might be anticipated that the adiponectin level be affected with coffee consumption. In conclusion, the study shows the long term use of caffeine is more efficient on blood sugar and adiponectin levels, which needed in the prevention of complications in diabetic subjects (Bhaktha G, Nayak BS, Mayya S et al.Relationship of Caffeine with Adiponectin and Blood Sugar Levels in Subjects with and without Diabetes. Journal of Clinical and Diagnostic Research. 2015, Vol-9(1):1-3).

THE AUTOIMMUNE CONSTELLATION IN LICHEN AMYLOIDOSIS

THE AUTOIMMUNE CONSTELLATION IN LICHEN AMYLOIDOSIS (Abstract): Localized cutaneous amyloidosis is a rare disease among white people, being more common in South-Asia, China and South America. The disease is characterized by deposition of amyloid material in the papillary dermis without visceral involvement. Nevertheless, there is a growing list of immune-mediated disorders that have been linked to cutaneous amyloidosis. We present two cases of concomitant occurrence of lichen amyloidosis and autoimmune thyroiditis/atopic dermatitis in two Caucasian women. **Keywords:** AMYLOIDOSIS, LICHEN AMYLOIDOSIS, HISTOLOGIC STAINS.

Lichen amyloidosis (LA) is defined as a chronic itchy skin condition, characterized clinically by the presence of hyperkeratotic papules and histologically by the deposition of amyloid in the papillary dermis. It occurs more frequently in males aged 50-60 years and is primarily located on the lower limbs, but the trunk or forearms can also be involved. The condition is the most common subtype of localized cutaneous amyloidosis (LCA), in which the protein is deposited only in the skin, without involving other organs (1).

Amyloidosis refers to the deposition of amyloid in various tissues and all clinical types of amyloidosis share a common amyloid P component: a nonfibrillar protein derived from a precursor known as serum amyloid P. Clinically, Shimizu classified amyloidosis into two major classes (2007):

- Systemic amyloidosis with 4 subtypes - systemic AL amyloidosis (AL stands for amyloid light chain), systemic AA amyloidosis, amyloid A being derived form α- globulin called serum amyloid A, familial systemic amyloidosis and hemodialysis-related amyloidosis.
- Localized cutaneous amyloidosis (LCA) with 2 major forms:
  - Primary localized cutaneous amyloidosis: lichen amyloidosis, macular amyloidosis, nodular localized cutaneous amyloidosis (amyloidosis cutis nodularis atrophicans), poikiloderma-like cutaneous amyloidosis, anosacral cutaneous amyloidosis
  - Secondary localized cutaneous amyloidosis - the deposition of amyloids is associated with another skin disorders (lichen simplex chronicus, verruca vulgaris, basal cell carcinoma, seborrheic keratosis, actinic keratosis etc).

What does the term *amyloid m*ean*?* The amyloid was defined in 1854 by Rudolph Virchow as the iodine-stainable starchlike which shares some common features such as eosinophilic amorphous appearance with hematoxylin – eosin stain (2).

LA is a rare, often misdiagnosed disease, which accounts for approximately 10% of cutaneous amyloidoses. In the past, the amyloid was considered to be a single substance regardless of the variation in clinical presentation. Nowadays, using the criteria of Congophilia and fibrillar morphology, more than 20 biochemically different forms of amyloid have been identified.

There are some special stains for the amyloid deposits, in addition to the classic Congo red: apple green birefringence, thioflavin T, crystal violet metachromasia, methyl violet, Pagoda red no.9, amyloid-P component antibody (3).

Although histologically LA involves amyloid deposits only in the papillary dermis, the epidermis is also involved, having as result the appearance of hyperkeratosis and acanthosis. The pathological examination usually shows massive deposits of amyloid in the dermis, highlighted by Congo red staining revealing amorphous appearance (4).

The etiology of LA is still a mystery, viral and genetic factors, feminine gender, atopy or local friction have been listed as possible triggering factors. The most affected areas are the shins or the extensor surfaces of the extremities, but involvement of the abdominal wall, anosacral region, scalp, ears, interscapular region or sites of varicose veins has also been reported (5-7).

CASE REPORTS

We present two cases diagnosed and treated at the Dermatology and Pathology Departments of the "St. Spiridon" University Hospital, Iasi, Romania in the interval January- April 2014.

Case 1 was a 50-year-old woman presenting with a history of intermittent pruritic, brownish papules, 4-5 mm in diameter, distributed bilaterally and symmetrically on the extensor area of the pretibial surfaces, (fig.1). Similar but smaller and flatter papules were also noted on the extensor surfaces of the arms. She had no previous skin disease and family history was negative. Case 2 was a 62-year-old female presenting similar papular and pruritic lesions but confined to the trunk. She had no family history of any similar dermatological disease. Thyroid function tests showed high TSH (thyroid-stimulating hormone) level

Fig. 1. Hyperkeratotic papules distributed on the pretibial areas

and normal T3 (triiodothyronine), T4 (thyroxine) levels. Anti-thyroid microsomal antibody was positive whereas antithyroglobulin antibody was negative. Routine complete blood cell count, blood chemistry, urinalysis and serum electrophoresis were within normal limits in both patients.

Initial differential diagnosis included: dyschromatosis pigmentosa reticularis, pretibial pruritic popular dermatitis, hyperkeratotic lichen planus, and pretibial thyroid dermopathy (also known as pretibial myxedema).

No evidence of systemic amyloidosis deposition was found.

A punch biopsy specimen of a papule was taken from the pretibial area (case 1) and from the trunk (case 2) for routine microscopic examination.

Results of histological examination showed epidermal acanthosis with hyperkeratosis associated pigment incontinence. Both cases had hematoxylin & eosin (H&E) stains available for review and paraffin blocks for immunohistochemical staining. The H&E slides were reviewed and the diagnoses were made using well-established histopathologic criteria. Special stains were performed: PAS, Congo red, Fontana, methyl violet and van Gieson. The Congo red stain was analyzed in polarizing microscopy.

Immunohistochemistry was performed on formalin-fixed, paraffin–embedded (4 - µm thick) sections using a standard technique (streptavidin– biotin – peroxidase technique) with appropriate positive and negative controls. Novocastra Multi Cytokeratin (clone AE1/AE3 cocktail ready to use) with Dako's En Vision system was used for detection.

In papillary and reticular areas an amorphous eosinophilic material was found. The deposits expanded the papillae and the elongated rete ridges were displaced laterally, without involving the vascular or adnexal structure (fig. 2). The amorphous deposits stained positive light red with PAS, Congo red, and methyl–violet (fig. 3), light yellow with van Gieson stain (fig. 4), and appear green to fluorescent yellow in polarizing microscopy (fig. 5). Fontana stain showed melanin pigment associated with the amorphous deposits and the increase pigmentation of the basal layer (fig. 6). Immunohistochemical stain with anti-keratin antibody demonstrated focal reactivity in amyloid deposits (fig. 7).

Based on the clinicopathological and laboratory findings, a final diagnosis of LA was made.

The treatment of LA is often difficult and the condition recurs frequently. Potent topical corticosteroids (with or without occlusive dressings), intralesional corticosteroids, topical calcineurin inhibitors, dermabrasion, PUVA and UVB phototherapy, systemic retinoids, cyclosporine or topical 10% of dimethylsulfoxide have been used for the medical management of LA (8,9).

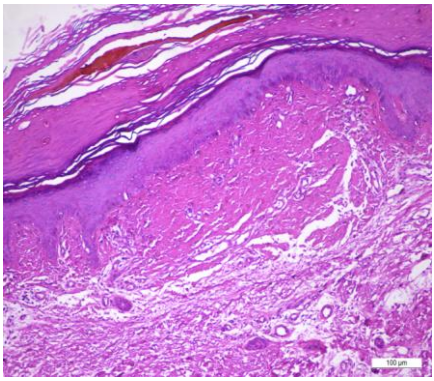

Fig. 2. Hyperkeratosis, elongation of the rete ridges and dermal papillary deposits of amorphous eosinophilic material, H & E, original magnification, x 200.

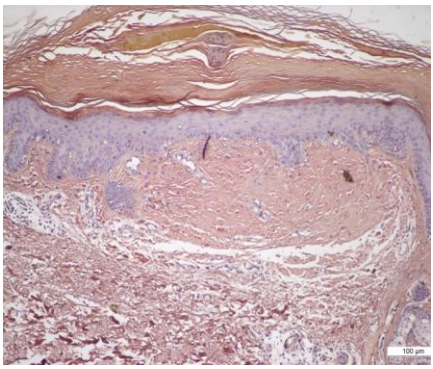

Fig. 3. Amyloids satin reddish brown in Congo red, original magnification, x 100

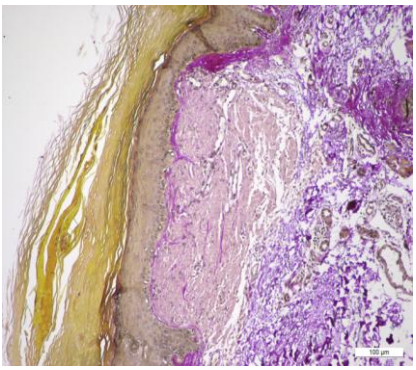

Fig. 4. Amorphous yellowish material, characteristic of amyloid in papillary and reticular dermis, van Gieson, original magnification, x 100.

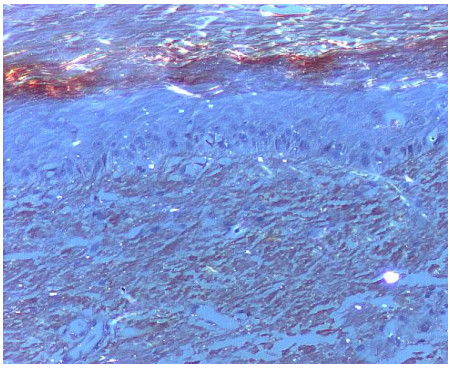

Fig. 5. Amyloid green to fluorescent yellow in polarizing microscopy, original magnification, x100.

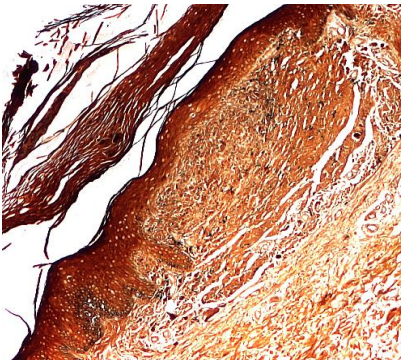

Fig. 6. Melanin pigment in amyloid deposit and basal layer, Fontana, original magnification, x40

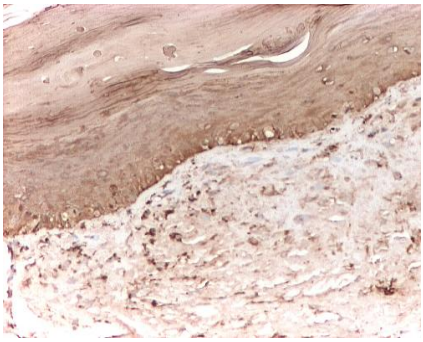

Fig. 7. Focal positivity in amyloid deposits for cytokeratins AE1/AE3, original magnification, x 200.

In our patients the treatment with oral antihistamine in association with topical applications of corticosteroids had a poor response.

DISCUSSION

In literature LA has been associated with a wide range of conditions: atopic dermatitis, dermatomyositis, systemic lupus erythematosus, autoimmune thyroiditis, hyperthyroidism and ankylosing spondylitis; however no association has been supported by statistically relevant data (10-13).

The differential diagnosis is often a challenge to many dermatologists, and we must always look for lichen simplex chronicus (affects predominantly females aged 30 to 50 years and clinically appears like chronically excoriated plaques), pretibial pruritic papular dermatitis (with a striking clinical resemblance to lichen amyloidosis but without amyloid deposition), pretibial thyroid dermopathy (a latter manifestation of thyroid disease), prurigo nodularis (hyperkeratotic nodules that vary in size from 0.5 to 3 cm), dyschromatosis pigmentosa reticularis (a rare genodermatosis characterized by generalized hyperpigmentation).

In lichen amyloidosis nerve fibers are localized at the dermoepidermal junction but not in the papillary dermis, suggesting that the pruritus may result from hypersensitivity of the nerve fibers that remain following the unexplained loss of nerves at the dermoepidermal junction. It is also possible that hyperthyroidism, by itching, may induce the occurrence or spread of LA (14).

Pigment incontinence, amorphous material and hyperkeratosis support the diagnosis of pruritic lesion, although non-pruritic variants of lichen amyloidosis have been described (15).

CONCLUSIONS

The histopathological findings in these two cases were similar to those reported in the literature, with amyloid depositing in the papillary and reticular areas and immunohistochemical staining positive for these deposits with antikeratin antibody AE1/AE3.

Lichen amyloidosis, the most common form of primary cutaneous amyloidosis, it is a rare disease among white people, with male predominance.

In our opinion, the occurrence of LA in two women, during a short period of time, in association with two autoimmune diseases is a strong indication that the etiopathogenic process is still unclear and that the genetic profile may be the strongest link to understanding the whole process.

NEWS

THE IMPORTANCE OF CYTOKERATIN 19 EXPRESSION IN THE DIFFERENTIATION OF BASAL CELL CARCINOMA AND TRICHOEPITHELIOMA

Basal cell-carcinoma (BCC) is the most common skin tumour constituting approximately 70% of all skin malignancies. It occurs mostly in the elderly especially in the head and neck regions in sun- exposed areas. It is a locally aggressive tumour with very rare metastatic rates. With immunohistochemical studies, it has been shown that BCC originates from follicular stem cells and basaloid epithelia of follicular projections of the hair buds. On the other hand, trichoepithelioma (TE) is a rare, benign tumour of skin adnexa originating from follicular germinative cells. They are commonly located on the face and hairy skin. There are three subtypes of TE: desmoplastic, solitary and multiple. Lesions are generally solitary and sporadic papules or nodules in skin color. They show similarities with BCC since they are formed from basaloid islands and cordons with peripheral palisading in fibrous stroma. In small skin biopsies, if morphological findings of BCC and TE are overlapping, differential diagnosis may be especially difficult. In previous studies, for the differentiation of these two tumours, some immunohistochemical markers such as CD10, bcl2, CK15, and Ber-EP4 have been used. In several studies, cytokeratin 19 (CK19) has been determined to have a high specificity for undifferentiated basaloid cells. CK19 is a small (40 kDa) acidic keratin that is expressed in germinative basaloid cells. In the non-neoplastic skin tissue samples, while positive staining with cytokeratin 19 in the outer root sheath of hair follicles and sweat glands were observed, there was no staining in basal layers. In conclusion, CK19 expression may be helpful in the differential diagnosis of BCC and TE especially in small skin biopsy samples in which morphologic differentiation is difficult (Bedir R, Sehitoglu I, Yurdakul C, et al. The Importance of Cytokeratin 19 Expression in the Differentiation of Basal Cell Carcinoma and Trichoepithelioma.Journal of Clinical and Diagnostic Research. 2015, Vol-9(1):1-4).

SEVERE HYPOTHYROIDISM IN OLDER PEOPLE: SPECIFIC FEATURES OF DIAGNOSIS AND TREATMENT. CASE REPORT AND LITERATURE REVIEW (Abstract): Prevalent causes of overt hypothyroidism are autoimmune destruction of the thyroid gland and previous thyroid surgery or radiation therapy. However, due to the side effects of amiodarone or lithium treatment thyroid dysfunction is increasingly frequent, especially in elderly patients who are anyway prone to a certain degree of hypothyroidism. This paper presents the case of a 66 years old patient who was admitted for severe physical asthenia and weight loss occurring during the past year. On admission we found anemia, which was considered secondary to a possible digestive tumor. The Comprehensive Geriatric Assessment (CGA) showed malnutrition, depression and a minor cognitive deficit. The absence of any obvious digestive cancer determined us to expand the investigation area. Cardiac ultrasound showed fluid in the pericardium which made us reconsider the diagnosis and take into account the presence of hypothyroidism, diagnosis that was subsequently confirmed by hormonal investigations and thyroid ultrasound. Hypothyroidism (either subclinical or overt forms) is a diagnosis that is easily overlooked in elderly patients because of its non-specific manifestations - symptoms may be wrongly attributed to normal aging or consequences of such diseases as depression, Parkinson or Alzheimer disease. Therefore, the measurement of serum thyroid-stimulating hormone (TSH) levels should be part of the biochemical work-up in all elderly subjects. **Keywords**: SEVERE HYPOTHYROIDISM, ELDERLY.

Hypothyroidism denotes deficient production of thyroid hormone by the thyroid gland. There are two clinical forms: subclinical and overt hypothyroidism (myxedema). Subclinical hypothyroidism is characterized by an elevated thyroid-stimulating hormone (TSH) level in the presence of normal serum free thyroxine (T4) and triiodothyronine (T3) concentrations. Subclinical hypothyroidism may progress to overt hypothyroidism in approximately 2-5% cases annually (1). The common causes of hypothyroidism are autoimmune destruction of the thyroid gland and previous thyroid surgery or radioiodine therapy, as well as various types of medication, including amiodarone, cytokines and lithium (2).

A mild degree of hypothyroidism is common in the elderly. It affects 5-20% of women and 3-8% of men. In elderly popu-

lation symptoms may be atypical: physical asthenia, lethargy, depression, cold intolerance, thinner skin and infiltration, especially around the face and hands, dilative cardiomyopathy and pericardial fluid. The heterogeneity of symptoms may mislead the diagnosis and delay the treatment; therefore measurement of TSH levels should be part of biochemical testing in elderly subjects and cases with TSH >10 mIU/L should be treated according to the cause and stage of the disease (2).

CASE REPORT

We present the case of a 66-year-old female patient from an urban area, who was admitted to the Geriatric Department because of severe physical asthenia and weight loss during the past year. The patient was diagnosed 2 years earlier with severe bradycardia possibly due to a sick sinus syndrome but not confirmed by ECG Holter monitoring; she had a type AAI pacemaker implanted anyway. The patient was also known with congestive gastritis and secondary anemia, treated at home with iron supplements.

On admission she presented severe physical asthenia, underweight (body mass index = 17), and the skin was pale, dry, hyper pigmented and thickened at face level. She had bradycardia (58/min) and a blood pressure of 90/60 mmHg. On palpation the abdomen was sensitive in the epigastrium where we found a mobile tumor of 3/4 cm. The deep tendon reflexes were bilaterally diminished and she presented paresthesia in her limbs.

The Comprehensive Geriatric Assessment (CGA) showed: malnutrition (MNA= 14/30), minor cognitive deficit (MMSE= 14/30) and moderate depression (GDS=7).

Blood tests showed mild anemia (Hb=10.2g/dl), dyslipidemia (Chol=281mg%, TG=160 mg%, LDL=180 mg%, HDL=30 mg%), stage 3 chronic kidney disease (creatinine clearance = 40.6ml/min/1.73m^2) and a lower tract urinary infection.

At that time we thought that the main cause for patient's symptoms was anemia due to several possible causes, such as: digestive tumor, chronic inflammatory process, responsible for the absence of response to iron supplements, or secondary to chronic kidney disease. While waiting for the examination of the digestive system, the patient presented sudden aggravation of the neurological symptoms (severe headache and delusions) associated with vomiting and severe secondary hyponatremia (Na=128.8 mEq/l). The absence of any obvious cause for the digestive manifestations and the persistence of neurological manifestations after the correction of sodium levels determined us to extend the investigations; cardiac ultrasound revealed the presence of fluid in the pericardium with preserved systolic function. Hypothyroidism would have been the ideal candidate to explain all the symptoms and hormone levels (TSH > 100 UI, fT4 = 0.15 ng/ml) and thyroid gland ultrasound (fig.1) (LTD: 1.0/2.3/1.2 cm (1.43 ml), LTS: 1.07/2.51/1.29 cm (1.80 ml), with hypoechogenic structure and low vascularization) confirmed the diagnosis.

Endocrinological assessment confirmed an autoimmune thyroiditis (AAT-TPO= 127 UI/ml vs N: < 34 UI/ml).

The substitution therapy with levothyroxine (Euthyrox) was introduced with gradually increasing doses and the course was favorable: disappearance of abdominal pain, neurological manifestations, depression and cognitive disorder and correction of hemoglobin levels.

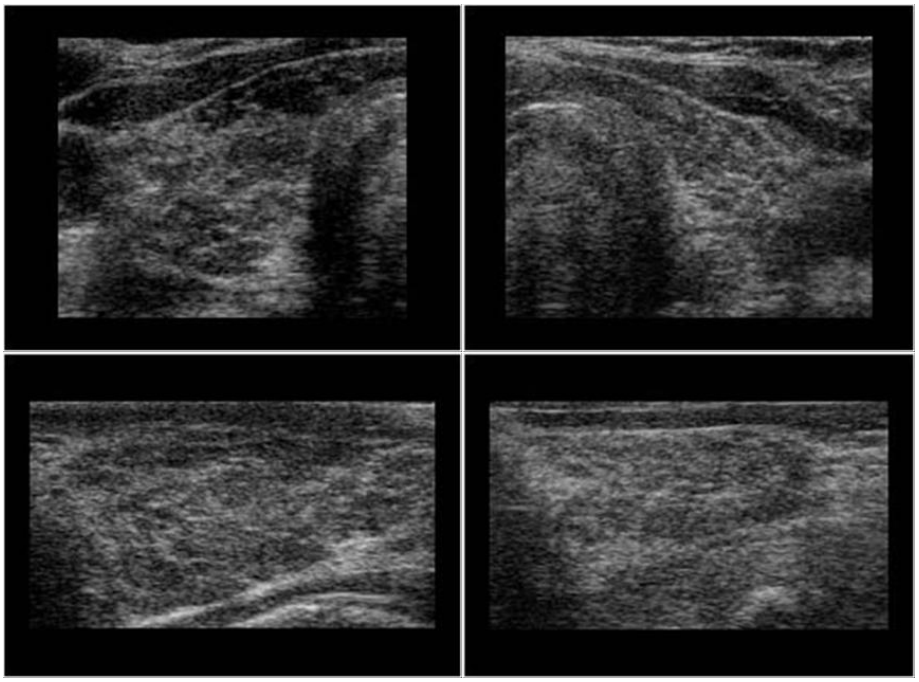

Fig. 1. Thyroid ultrasound – appearance characteristic for autoimmune thyroiditis

DISCUSSION

The first cases of myxedema were reported in the literature more than 90 years ago when the effects of the thyroid hormones upon the heart (heart failure and dilative cardiomyopathy) were discovered. The first case of third degree atrioventricular block secondary to hypothyroidism was described in 1918 (Aub and Stern, 1918, cited by 3), and by 1930 there were 21 reported cases of hypothyroidism with secondary heart diseases (heart failure refractory to digitalis therapy, atrioventricular blocks of different degrees, pericarditis and cardiomegaly) (4). Schantz and Dubbs (cited by 5) reported a similar case in 1951, with adequate sinus rhythm after hormone replacement therapy. Over the years there were few reports of isolated cases of overt hypothyroidism, and they focused mainly on episodes of myxedema coma.

Hypothyroidism mainly affects women and the elderly (6). In elderly population this disorder is frequently associated with such drugs as amiodarone and lithium (7). The symptoms may be atypical and might be considered more likely secondary to aging than due to hypothyroidism, especially if there is no previous medical or pharmacological information available. The neurological manifestations occur in most of the cases: physical asthenia, bradypsychia or even different degrees of cognitive dysfunction, paresthesia, and depression. The carpal tunnel syndrome is very frequent, and the deep tendon reflexes are usually modified (8). The cardiac manifestations are insidious, manifested by the progressive increase in size of the heart cavities, episodes of left ventricular failure and pericarditis, which are unresponsive to

diuretic and digitalis treatment. ECG appearance varies from sinus bradycardia with nonspecific modifications of ST segment and T wave to third degree atrioventricular block or the torsades de pointes (9, 10, 11). Due to this heterogeneity of symptoms, the disease can progress for a long time under various other diagnoses and therapeutic schemes as it was the case of our patient, who was even treated for a possible sick sinus syndrome with the help of a pacemaker. Moreover, the persistence of digestive symptoms needed further investigations, such as endoscopy and colonoscopy, as persistent anemia highly suggested the presence of a digestive tumor.

Unlike the severe form, subclinical hypothyroidism is relatively frequent in the general population (15% in women and 10% in men) (12). Unfortunately, the onset of the disease in the geriatric patient may be wrongly attributed as manifestations of other diseases such as depression, Parkinson disease (7) or Alzheimer disease. The existence of co-morbidities and poly pharmacy may mask the symptoms and signs of hypothyroidism and delay the correct diagnosis and proper treatment.

The most important feature of subclinical hypothyroidism is the increased likelihood (2-5%) to progress to overt hypothyroidism, the progress rate being proportional to TSH level. It was hypothesized that subclinical hypothyroidism would be a risk factor for cardiovascular disease (13).

The decision to treat the elderly patients with subclinical hypothyroidism is still controversial. A review published in 2007 (13), including 12 trials involving 350 patients monitored for 6 to14 months, concluded that hormone replacement did not result in improved survival or decreased cardiovascular morbidity. The present consensus (1) for the elderly patients is that replacement therapy should be carefully considered due to the high risk for cardiovascular side-effects: tachycardia or aggravation of stable angina. Patients with subclinical hypothyroidism should be informed about the disease and its clinical manifestations and serum TSH level should be measured once or twice a year.

The recommended and appropriate replacement therapy for overt hypothyroidism is levothyroxine sodium. In elderly patients the initial dose should be smaller if there is any concomitant heart disease: 12.5 to 25 µg/day. Replacement dose titration should be cautious with close monitoring of patient symptoms and thyroid function tests. Because of the long half-life of levothyroxine sodium, small dosage adjustments may be performed at 6-week intervals by an increment of 12.5 to 25 µg until serum TSH is in the mid-normal range. After that, its measurement may be done every 6 to 12 months to monitor the dose and compliance (14). Thyroid hormone therapy has no beneficial effect above placebo in elderly individuals with normal serum TSH and T4 levels. The major risk of levothyroxine sodium therapy is over-replacement, with anxiety, muscle wasting, osteoporosis and atrial fibrillation as adverse effects.

CONCLUSIONS

This article draws attention on the polymorphism of signs and symptoms associated with myxedema in elderly patients. The risk to overlook hypothyroidism is high and may lead to unnecessary procedures, as was in our patient the pacemaker implantation for an AV block which could be managed only with thyroid hormone therapy.

Hypothyroidism should be the first diagnostic assumption should we deal with patients under treatment with amiodarone and/or lithium, largely used in treating cardiovascular and neurological diseases highly characteristic for elderly. Hypothyroidism should be suspected in all patients with second and third degree atrio-ventricular block of unknown cause, refractory heart failure and idiopathic pericarditis.

Treatment for overt hypothyroidism was initiated immediately after the diagnosis was confirmed with excellent outcome; however, treatment should be closely monitored to avoid over-replacement.

BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM. - A RAPIDLY EVOLVING ENTITY. CASE REPORT (Abstract): blastic plasmacytoid dendritic cell neoplasm (BPDCN), CD4+/CD56+hematodermic neoplasm was formally known as blastic NK-cell lymphoma. It is in fact a form of acute myeloid leukemia notable for highly aggressive behavior with cutaneous, lymph node and bone marrow involvement. This entity is derived from plasmocytoid dendritic cells and has a predilection for extranodal sites, especially the skin. Elderly male patients are the most affected and the prognostic is poor. The first case was reported in 1994 and sice then, single cases and a few small series have been published. This article presents the case of a previously healthy 56-years-old man, who presented himself to a skin eruption consisting in multiple, large dermal ulcerated tumors, located on the trunk and scalp. The lesions were painless and grew in size rapidly. Physical examination was normal except for the skin lesions. Histological examination of a biopsy specimen and immunohistochemical studies (positive for next markers: CD4, CD 45, CD56, CD68, Ki 67) revealed the rare diagnostic - blastic plasmacytoid dendritic cell neoplasm. **Keywords:** BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM, CD4+/CD56+ HEMATODERMIC NEOPLASM, IMMUNOHISTO-CHEMISTRY, SKIN CANCER.

Blastic plasmacytoid dendritic cell neoplasm (BPDCN) it is a rare disease, more prevalent in Asia and Latin America than in Europe, with predominance in males (1). Over the past decades, the understanding the biology of lymphoid cells has improved and so has the knowledge of primary cutaneous lymphomas. The current World Health Organization/ European Organization of Research and Treatment of Cancer (WHO/EORTC) classifications are based on clinical, pathological, immunopathological, molecular and cytogenetic findings. The hematodermic neoplasm is defined as a separate entity, CD4+/CD56+ hematodermic neoplasm (2). NK are a variety of cytolytic cells capable of killing a different target cells such as bacteria/viruses, infected cells or tumor cells (3). CD4+/CD56+ hematodermic neoplasm is an extremely rare, very aggressive form of acute myeloid leukaemia. Due to its rapid fatal course, no clinical trial has been conducted and the therapeutical options are

based on small retrospective cohorts of patients (4). Generally this type of lymphoma has a skin-tropism, with clinical presentation in the form of papules or nodules that vary in appearance and affects elderly adults, although BPDCN without cutaneous lesions has been described (5).

We report the case of a 56 years-old man, with CD4+/CD56+ hematodermic neoplasm, with rapid degradation of clinical status and severe reaction to the chemotherapy.

CASE REPORT

A 56-years-old man was admitted in the Dermatology Department of "St. Spiridon" Universitary Emergency Clinical Hospital, Iaşi with the suspicion of *Mycosis fungoides.* The clinical examination revealed many cutaneous painless tumors on the trunk and scalp, 5/10 cm in size, ulcerated, which appeared in the last 2 months and which rapidly, grew in size. Bilateral inguinal lymph node enlargement (less than one cm in diameter) was noted in physical examination. The patient was at first assessed in another hospital center, for red macules and joint pain, and was treated with corticosteroids. The lesions reappeared after he interrupted the treatment while the tumors progressed rapidly and became necrotic (fig. 1).

Fig. 1. Clinical aspects of dermal necrotizing tumors, with rapid progression

Laboratory data revealed: white blood cell count was 2.97 x 10^9 cells (neutrophils 9.8%, lymphocytes 63.6%, monocytes 19.5%, basophiles 5.4%), hemoglobin level 12.1 g/dl, albumin level 51.2%, C-reactive protein (CRP) level was 1.52 mg/dl, and lactate dehydrogenase (LDH) level, 602 IU/l.

Computerized tomography showed:

- right parieto-occipital lesions involving the brain (fig. 2);
- dermal tumors on the anterior surface of the chest; note the presence of air bubbles within the tumor volume (fig. 3);
- systemic involvement of lymph nodes, especially in the armpit and inguinal areas;

- many cutaneous, expansive nodules, disseminated on the hole scanned area, but most consistent and larger in chest area;

- heterogenous gas bubbles structure, calcification and contrast enhancement in the solid component of the tumor.

Fig. 2. Brain lesions

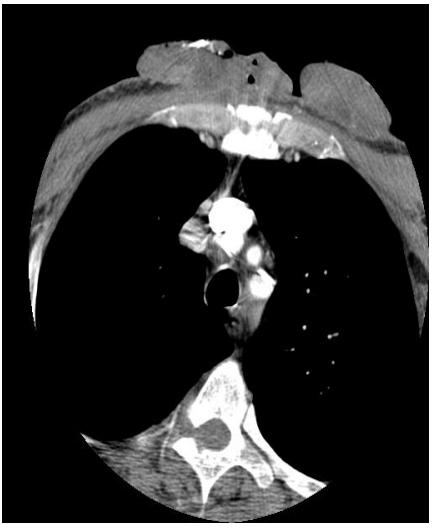

Fig. 3. Dermal tumors on the chest

A skin biopsy was performed and pathologic exam established the final diagnosis. The immunohistochemical examinations showed diffuse dermal infiltration with neoplastic cells, showing blastoid morphology and positive reaction for: CD4, CD45, CD56, CD68, and Ki 67, whereas CD3, CD30, CD5, CD8 and CD15 were negative.

Figure 4-tumor cells with intense CD4+ staining (ob.x 20), figure 5 -tumor cells with intense CD56+ staining (ob.x 40) and figure 6 with skin biopsy showing diffuse dermal infiltration with tumor cells.

Based on pathological findings, the final diagnosis was cutaneous CD4+/CD56+ hematodermic neoplasm, with systemic involvement. The patient began chemotherapy using a regimen combining vinblastine, lomustine and etoposide. After 14 days of chemotherapy, low neutrophil counts were detected, the chemotherapy was stopped and filgastrim treatment was initiated. The second day, the patient was found unconscious, with no reaction to verbal stimulus, and he was transferred to the Intensive care Unit. His recovered was slow after supportive treatment, correction of acid-base and hydro-electrolytic imbalance, mannitol, methotrexate, calcium folinate, phenobarbital and carbamazepine. Two weeks later his neurological status returned to normal, there were no neurological focal signs or evidence for brain bleeding. He was transferred back to Hematology Clinic and the therapeutic program was reconsidered with methotrexate. The oncology committee decided to start radiotherapy but during these sessions the patient became highly agitated, bewildered and aggressive and is treated with anti-edematous, phenobarbital, valium and haloperidol. The skin lesions were diminished rapidly and the patient was discharged.

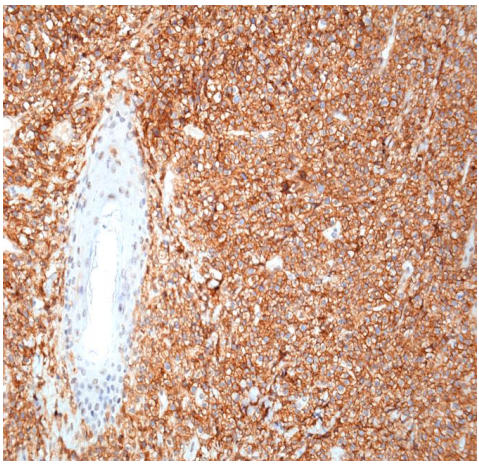

Fig. 4. Tumor cells with intense CD4+

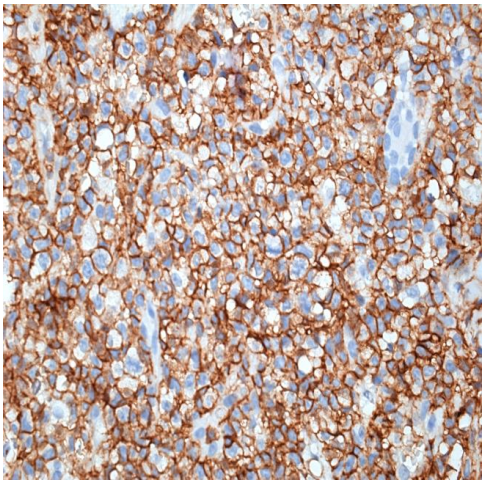

Fig. 5. Tumor cells with intense CD56+

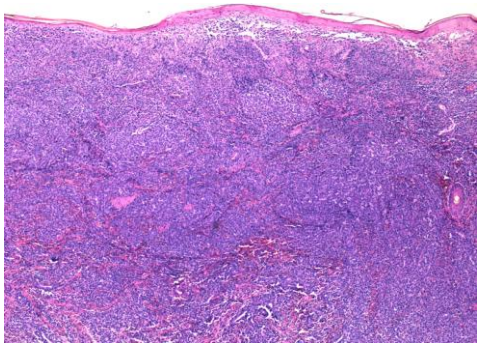

Fig. 6. Skin biopsy showing diffuse dermal infiltration with tumor cells.

After only one month, the patient's state worsens and deceases with multiple organ and system failure.

DISCUSSION

BPDCN is characterized by positive results for CD4, CD43, CD56, CD68 and CD123 and negative results for conventional myeloid and lymphoid T and B-cell markers with involvement of the skin in the most cases. Recently, these immunophenotypical characteristics lead to the new terminology, BPDCN, instead of the blastic NK-cell lymphoma.

It has been thought that these cells arise from NK progenitor cell, but most recent studies suggested that the origin is a lymphoid related plasmocytoid dendritic cell. This idea is sustained by the expression of the blood dendritic cell antigen 2 (BDCA2) and interleukin-3 receptor alpha subunit (CD123) (6, 7).

As in others forms of leukemia, the atypical presentation is very common, the median survival rate is low, in this case about 12-14 months, so recognizing the clinical, pathological and immunohistochemical features are very important for finding a promising treatment (8, 9).

The differential diagnosis must include nasal type NK-cell lymphomas, cutaneous T-cell lymphomas and CD 56^{+} acute myeloid leukemia.

Mycosis fungoides, our first suspicion, is distinguished from BPDCN by the presence of epidermal involvement and $CD3^{+}$, $CD56^{-}$ immunophenotype.

CONCLUSIONS

In our opinion, at this moment there is no consensus for the optimal treatment of BPDCN. Myeloablative treatment with allogenic bone marrow transplantation, within the first episode of remission has

resulted in a better survival (10). Other promising options are immuno-therapy with interleukin-3or CD123 antibody. In conclusion, dermatologists must become aware of this rare form of leukemia and more informed about the use of CD cell markers in the field of cutaneous oncology.

INCIDENCE AND RISK FACTORS OF *CLOSTRIDIUM DIFFICILE* INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE (Abstract). Recent changes in the epidemiology of *Clostridium difficile* infection (CDI) include the identification of patients with inflammatory bowel disease (IBD) as a group at risk in comparison to the general population. **Aim**: To identify the incidence and risk factors for CDI among patients with IBD. **Material and methods**: Case-control study of 78 patients diagnosed with IBD, hospitalized at the Iasi Institute of Gastroenterology and Hepatology between January 2012 and -July 2014. Demographic data and clinical characteristics were reviewed for all patients. IBD patients with positive *C. difficile* toxins A and B tests were matched by sex, age and type of IBD with IBD patients hospitalized in the same period with negative *C. difficile* toxins tests. **Results:** Both groups were comparable for baseline characteristics. Of the 78 patients diagnosed with IBD included in the study, *C. difficile* was detected in 26 patients (33.33%). There was no statistical difference regarding length of hospital stay (10.42±7.34 *vs.* 8.01±6.14 days, p=0.129) between the two study groups. Risk factors for CDI in patients with IBD were: ulcerative colitis (OR=1.90, CI= 1.320-2.720, p=0.001), use of proton pump inhibitors (OR=1.57, CI=1.133-2.032, p=0.012), previous antibiotic use (OR=2.3, CI=1.587-3.332, p<0.0001), and albumin<3g/dl (OR=1.78, CI=1.023-5.558, p=0.038). Immunosuppressive and anti TNF-α treatment were not risk factors for *C. difficile* development in patients with IBD. **Conclusions**: CDI in patients with IBD is a serious infection and should be treated aggressively with close clinical follow-up. Ulcerative colitis, previous treatment with antibiotics and proton pump inhibitors represent risk factors for CDI development in patients with IBD. **Keywords:** *CLOSTRIDIUM DIFFICILE*, RISK FACTORS, ULCERATIVE COLITIS, INCIDENCE.

Recently there has been an increase in both incidence and severity of *Clostridium difficile* infection (CDI) worldwide (1). Recognized risk factors for infection include advanced age, broad-spectrum antibiotic therapy, prolonged hospitalization, malignancies (2), immunosuppression, the use of proton pomp inhibitors and the presence of multiple co-morbidities (3, 4).

Several studies demonstrated an increasing incidence of CDI in patients with underlying inflammatory bowel disease (IBD), with a more severe course of the disease compared with the non-IBD population (5-9). The incidence of CDI among hospitalized IBD patients increased from

1% in 1998 to 3% in 2007 (10). Both ulcerative colitis (UC) and Crohn's disease (CD) present high-risk for CDI, but patients with UC are more susceptible than those with CD (11,12).

Besides traditional risk factors for CDI, IBD patients present specific risk factors, unique to IBD, in relation to colonic involvement and disease severity, and it seems that IBD itself is an independent risk factor for CDI. In a study by Issa et al., colonic involvement and pancolitis were associated with a threefold greater risk (5), concluding that the extent and severity of the disease may be considered independent risk factors for CDI development in patients with IBD.

CDI has a negative impact on IBD course and is associated with a significant increase in need for colectomy and mortality (13). Therefore, in the present study we aimed to evaluate the incidence and the risk factors associated with CDI in IBD patients admitted in a tertiary center.

MATERIAL AND METHODS

Patients. We conducted a prospective, case-control study on IBD patients admitted to the Iasi Institute of Gastroenterology and Hepatology in the interval January 2012- July 2014.

Demographic data and clinical characteristics like comorbidities, previous antibiotic use, immunomodulators, acid suppression, length of hospital stay, gastrointestinal surgery and outcome were assessed. Patients with indeterminate colitis, other infectious colitis and sepsis were excluded.

Diagnosis of CDI. All patients with flare activity were tested using immunochromatography assays for toxins A and B. Patients who tested positive for *C. difficile* toxins A and B were identified (n=26) and matched with IBD patients with negative *C. difficile* toxins (n=52) hospitalized during the same period of time.

Statistical analysis. The statistical analysis was carried out using the SPSS 17.0 software (SPSS Inc., Chicago, IL, USA). Continuous data were expressed as mean +SD and categorical data as percentage. The Kolmogorov-Smirnov test was used to determine whether the continuous variables were normally distributed. Analysis of variance and the chi-square test were used for continuous and categorical variables, respectively. The Student t test or Mann-Whitney U test were used to compare groups, with the chi-square test used for categorical variables. Risk factors for CDI in patients with IBD were determined using logistic regression for univariate analysis. A p value of less than 0.05 was considered statistically significant.

RESULTS

Incidence of CDI. Baseline demographic, clinical, and laboratory characteristics of the study population are outlined in Table I. There was no significant difference between the 2 study groups.

During the study period, a total of 78 patients were admitted with the diagnosis of IBD of whom 26 (33.3%) had concomitant CDI. Of the IBD patients, 43(55.1%) had UC, and 35(44.8%) had CD.

We assessed the annual incidence of CDI in patients with IBD and found that it increased from 2.01% in 2012 to 16% in 2014 (fig.1). Likewise, UC patients were more susceptible to CDI than CD patients (fig.2).

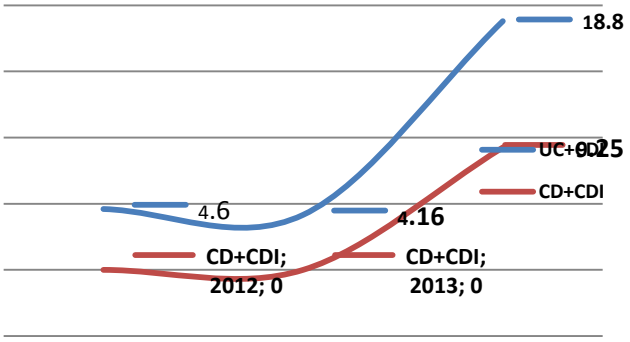

Fig. 2. Annual incidence of CDI in patients with UC and CD

Risk factors for CDI. Antibiotic use prior to CDI was reported in 43 patients (55.1%), the most commonly used antibiotics being ciprofloxacin (36.1%) and ampicillin (19%) for urinary tract and upper respiratory tract infections. In our study, the length of hospital stay was not influenced by CDI (10.42±7.34 vs. 8.01±6.14, p=0.129) (tab. II).

C. difficile infection was more common among patients with a recent diagnosis of IBD. Likewise, patients with an IBD flare-up were more susceptible to CDI (8.07±4.48 *vs.* 3.94±3.13, p<0.0001) (fig. 3). Cardiovascular co morbidities and malignancies did not influence the risk for CDI in our study population.

In our study, IBD patients with CDI were treated with metronidazole 250 mg orally four times daily for 10 days. In case of metronidazole failure vancomycin treatment was initiated. This was required in 2/26 (7.69%) patients. In this study the rate of CDI recurrence was 16%.

TABLE II

Risk factors for CDI

Parameter	OR	IC 95%	p
ulcerative colitis	1.90	1.320-2.720	**0.001**
proton pump inhibitors use	1.57	1.133-2.032	**0.012**

DISCUSSION

A dramatic increase in CDI has been documented over the last two decades (5-9). Today, CDI is recognized as the main cause of infectious nosocomial diarrhea associated with increased morbidity, mortality and healthcare costs (14).

Several studies have reported a significantly increased incidence of CDI among IBD patients, particularly in those with UC. Thus, a study using nationwide data showed that in US the incidence of CDI among hos-

pitalized UC patients has doubled over a 7-year period (15). Likewise, a Belgian study reported a nearly four-fold increase in CDI in both IBD and non-IBD patients between 2000 and 2008 (8). Our results showed that the incidence of CDI in IBD has increased during the study period for which data were available. Also, CDI is significantly more common in UC than in CD.

The classical risk factor for CDI is exposure to broad-spectrum antibiotics. Antibiotics disturb the normal intestinal flora, allowing *C. difficile* to proliferate (16). In this study, we found that previous antibiotic therapy and previous proton pump inhibitors treatment represent risk factors for CDI development in patients with IBD. Additionally, immunosuppressive and anti-TNF-α treatments were not risk factors for CDI.

Contrasting results have been reported regarding the length of hospital stay in IBD patients with CDI. Jodorkovsky et al. (11), reported a similar mean length of hospital stay for UC patients with and without superimposed CDI (11.7 *vs.* 11.0 days; p = 0.70), while Bossuyt et al. (8) found notably shorter stays in IBD patients with CDI (mean 15.2 days) as compared to non-IBD patients with *C. difficile* (mean 27.7 days) (<0.001). Our data support that the length of hospital stay is not influenced by the presence of CDI.

Our findings suggest that CDI is more frequent in patients who present with IBD flare-ups. Therefore, clinicians should maintain a high index of suspicion for CDI in IBD patients, especially in those with UC.

Recurrence of CDI is present in 10-30% of IBD patients (16). In this study the rate of CDI recurrence was 16%. This is in agreement with previous studies that reported similar findings.

A major limitation of our study may be the small number of patients and the fact that it was a single center study. This could have an influence on the conclusions regarding risk factors. Another limitation of this study is the absence of routine CDI testing in all patients with IBD as in other studies, and this could have influenced the annual incidence rate of CDI.

CONCLUSIONS

Our results show that the risk of CDI in IBD patients is extremely high and the incidence appears to be increasing at a faster rate. IBD patients who present with symptoms of a flare must be tested for *C. difficile* toxins. A rapid and adequate diagnosis and treatment may improve prognosis in IBD patients.

NEWS

THE STRUCTURE OF IBUPROFEN BOUND TO CYCLOOXYGENASE-2

Cyclooxygenases (COX-1 and COX-2) catalyze the rate-limiting step in the biosynthesis of prostaglandins, prostacyclins, and thromboxanes and are the pharmacological targets of non-steroidal anti-inflammatory drugs (NSAIDs) and COX-2 selective inhibitors (coxibs). One of the most commonly available over-the-counter pharmaceuticals in the world is ibuprofen. The anti-inflammatory and analgesic properties of ibuprofen are thought to arise from inhibition of COX-2 rather than COX-1. Ibuprofen occupies an area of the enzyme between the substrate channel opening and the apex of the active site. While an X-ray crystal structure of ibuprofen bound to COX-1 has been solved, no such structure exists for the cognate isoform COX-2. Almost all interactions formed between ibuprofen and the active site residues of COX-2 consist of hydrophobic interactions. A group of researchers have determined the crystal structure of muCOX-2 with a racemic mixture of (R/S)-ibuprofen and the study reveals that only the S-isomer of ibuprofen was bound resulting that the S-isomer possesses higher affinity for COX-2 than the R-isomer. The structure clearly reveals that S-ibuprofen is bound with full occupancy in both monomers of COX-2. The results provide the first atomic level detail of the interaction between ibuprofen and COX-2 (Orlando BJ, Lucido MJ, Malkowski MG. The structure of ibuprofen bound to cyclooxygenase-2. *J Struct Biol* 2015; 189: 62-66).

EXERCISE-BASED REHABILITATION FOR METABOLIC SYNDROME - CASE REPORT (Abstract): Physical activity is a key part of cardiac rehabilitation, especially in patients with metabolic syndrome. Recent reports suggest that high-intensity interval training is more effective than continuous moderate intensity training, classically employed in cardiac rehabilitation programs. However, the implementation of a standard training protocol aimed at achieving a target heart rate during exercise can be limited by exaggerated pressor response, especially in deconditioned subjects. We report the case of a 47-year-old male with metabolic syndrome who was enrolled in a one-year exercise based-cardiac rehabilitation program. We implemented a two-phase protocol, starting with 5 continuous training sessions at 25 W, during which we gradually increased exercise duration up to 30 minutes. The second phase of the program consisted of biweekly interval training sessions of 25-50, 50-75 and finally 75-100 W. The switch to higher workloads was made only after the patient presented appropriate pressor response adaptation to current training intensity. Our program positively influenced our subject`s cardiovascular risk factors and allowed discontinuation of antihypertensive drug therapy. **Keywords**: CARDIAC REHABILITATION, METABOLIC SYNDROME, INTERVAL TRAINING.

At least 3-5 weekly sessions of physical activity (150 minutes of moderate intensity or 75 minutes of vigorous physical exercise) decrease all-cause mortality and positively influence cardiovascular risk factors, including the incidence of metabolic syndrome (MS) (1, 2, 3). MS is not only more prevalent in patients with cardiovascular disease, but also an independent risk factor for higher morbi-mortality rates among these patients (4). It is estimated that half of the patients referred to cardiac rehabilitation suffer from metabolic syndrome, and several studies have shown an improvement of all MS diagnostic criteria after cardiovascular rehabilitation. The fact that short-term effects of cardiac rehabilitation appear to be more spectacular than the long-term results can be due to poor long-term adherence to lifestyle changes (5).

The level of physical activity is inversely correlated to metabolic syndrome incidence, making it one of the most important components of cardiac rehabilitation pro-

grams (6). Performing cardiopulmonary exercise (CPX) testing when enrolling a patient in a rehabilitation program allows an objective assessment of the subject`s physiologic response to exercise and plays a key part in risk stratification and determining optimal exercise training intensity. CPX test results include peak $VO_2$ – a marker of the patient`s functional capacity, the anaerobic threshold – which guides exercise prescription, respiratory exchange ratio and oxygen pulse. CPX testing is particularly useful in patients on beta-blocker treatment, in which the Karvonen method (using heart rate reserve in prescribing target heart rate during exercise) should not be employed (7).

Patients with cardiovascular disease are usually recommended moderate intensity exercise at 60-80% of the maximum heart rate or anaerobic threshold. Recent reports suggest that high-intensity interval training is more efficient than classical moderate-intensity continuous training (8). According to another report, even 51 minutes per week of high intensity interval training was as effective as 150 minutes per week of moderate intensity continuous training in patients with metabolic syndrome (9). Further studies are needed to determine the most effective length of the high intensity interval bout as well as the optimal weekly volume of training.

CASE REPORT

CD, a 47-year-old male, was referred to the local Cardiovascular Rehabilitation Clinic for exercise testing and exercise-based rehabilitation for grade II arterial hypertension. His past medical history also included obesity, mixed dyslipidemia and a positive family history of hypertension and diabetes. The patient met the criteria for metabolic syndrome: class 1 abdominal obesity (Body Mass Index 34.1, waist circumference 118 cm) elevated fasting glucose (112 mg%), hypertriglyceridemia (209 mg%), hypertension (165/100 mmHg on admission), so we decided to start treatment with a low dose angiotensin converting enzyme inhibitor.

During the cardiopulmonary stress test our patient achieved a maximum workload of 120 W (59% of predicted value), with a peak oxygen uptake (VO_2) of 1719 mL/min (62% of predicted value) and anaerobic threshold of 1710 mL/min (17.6 mL/kg/min), suggesting a slight reduction of functional capacity (Weber class A). The test was halted after 11 minutes due to uncontrolled blood pressure (BP) values (230/120 mmHg), although our previous Ambulatory Blood Pressure Monitoring (ABPM) illustrated appropriate blood pressure control (mean 24h-Systolic BP 115 mmHg, mean 24h-Diastolic BP 71 mmHg, max-BP 150/125 mmHg, 24h systolic abnormal ratio 2.8%, dipping index 18%).

Our patient was enrolled in an exercise-based rehabilitation program, consisting of biweekly 30-minute sessions of aerobic resistance training on a bicycle ergometer under the supervision of a certified kinesiotherapist. The first phase of rehabilitation consisted of 5 sessions during which we progressively increased cycling duration from 10 to 30 minutes. This was performed at a continuous workload of 25 W. We started the second phase training sessions with 2.5-minute warm-up followed by five sets of 4-minute cycling at 25 W and 1-minute training at 50 W, ending with a 2.5-minute cool-down. The work-out intensity was gradually increased according to protocol (tab. I). The switch to higher workloads (50-75W and 75-100W after 1 and 5 months, respectively), was determined by patient's pressor response during exercise.

TABLE I

Interval training protocol

	2.5-minute warm-up	5 x 5 minutes training sequences of:	2.5-minute cool down	Exercise duration
25-50W	10 W	4` - 25W + 1` - 50 W 3` - 25W + 2` - 50 W 2` - 25W + 3` - 50 W 1` - 25W + 4` - 50 W	10 W	30 minutes
50-75W		4` - 50W + 1` - 75 W 3` - 50W + 2` - 75 W 2` - 50W + 3` - 75 W 1` - 50W + 4` - 75 W		30 minutes
75-100W		4` - 75W + 1` - 100 W 3` - 75W + 2` - 100 W 2` - 75W + 3` - 100 W 1` - 75W + 4` - 100 W		30 minutes

A second cardiopulmonary stress test was performed after 1 year of exercise-based physical rehabilitation, with significantly improved results (maximum workload 178 W, 86% of predicted value, VO_2 max 2174 mL78% of predicted value, oxygen pulse 17 mL/min). Our patient`s cardiovascular risk markers also showed gradual improvement during the 1-year follow-up (tab. II), allowing the withdrawal of previous angiotensin converting enzyme inhibitor treatment.

TABLE II

Evolution of clinical and biological parameters during the one-year follow-up

	Baseline value	Months 3	6	12
Weight	108	106	103	98
Waist circumference	118	117	114	110
Triglycerides	209	180	103	92
Total cholesterol	209	180	151	160
Low density lipoprotein cholesterol (LDL)	113.2	83	55	57.6
Glycemia	112	108	103	98
Systolic BP	165	132	130	117
Diastolic BP	100	92	79	68
Resting Heart Rate	92	86	72	65

DISCUSSION

High intensity training has proven more effective than continuous moderate intensity training standardly used in cardiac rehabilitation. Although several training protocols have been studied and published (8), the implementation of a standard, universal protocol, aimed at achieving a target heart rate during exercise is often limited by patient`s exaggerated pressor response, as

illustrated in our case report.

During the first CPX testing, our patient rated the perceived exertion as "somewhat hard" (Borg scale 13) but the test was halted after 11 minutes due to high blood pressure (230/120 mmHg). Although according to our subject`s test results (maximum workload 120 W, Weber class A) we could have begun the phase I trainings at a 50 W workload, our patient presented an exaggerated pressor response after just 4 minutes of training (BP 200/110 mmHg) forcing us to decrease initial continuous exercise workload to 25 W. Cycling duration at 25 W was also limited by high blood pressure values (127/72 mmHg at baseline, 160/100 mmHg after 4 minutes and 170/100 after 10 minutes), requiring 5 sessions in which we gradually increased exercise duration from 20 to 30 minutes thus allowing pressor response adaptation.

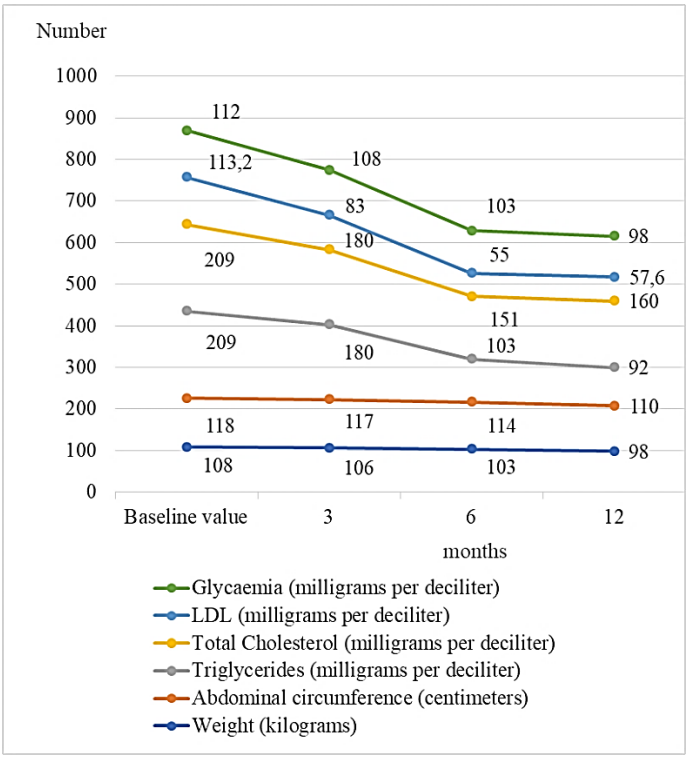

Fig. 1. Beneficial effects during 1 year of exercise rehabilitation: weight, triglycerides, LDL, waist circumference, total cholesterol and fasting glucose have all improved by 9.2%, 55.9%, 49.11%, 6.7%, 23.4% and 12.5%, respectively.

Our two-phased training protocol ensured that the patient maintained adequate blood pressure values during work-out and permitted the switch to higher workload exercise sessions only after achieving appropriate pressor response adaptation to current exercise intensity (blood pressure during peak workload interval below 140/90 mmHg). Our approach has proven as effective as other rehabilitation protocols (5) in

reducing the patient`s resting heart rate (by 29%, 27 beats per minute), systolic and diastolic blood pressure values (by 29 and 32%, respectively), thus allowing withdrawal of the antihypertension medication. After one year of exercise-based cardiac rehabilitation our subject no longer meets the metabolic syndrome criteria, exhibiting a 12.5% decrease in fasting glucose, a 55.9% decrease in serum triglycerides as well as a 6.7% decrease in waist circumference, now below the 102 cm threshold (fig.1).

Patient adherence is still an unresolved issue in cardiac rehabilitation (8). However, our individualized exercise protocol was enthusiastically received by our patient, who was present for 82% of his scheduled sessions, an excellent adherence rate compared to those reported in other studies (8). We believe that our 3- and 6-month check-ups contributed to this high adherence rate as it allowed the patient to acknowledge his progress.

CONCLUSIONS

The intensity of interval training in our patient was limited by exaggerated pressor and chronotropic response to relatively low exercise workload, although according to the cardiopulmonary exercise test our subject presented mildly altered functional capacity (Weber class A). Our patient with metabolic syndrome benefited from long-term exercise-based cardiac rehabilitation but required an individualized exercise protocol.

BUTYRYLCHOLINESTERASE ACTIVITY – BIOMARKER FOR PREDICTING THE OUTCOME IN ACUTE CHOLINESTERASE INHIBITOR POISONING – A 30-YEAR RETROSPECTIVE ANALYSIS (Abstract): **Aim.** To assess the role of butyrylcholinesterase (BuChE) activity as a predictive biomarker in acute cholinesterase inhibitor poisoning in a cohort from a regional tertiary care hospital. **Material and methods:** Plasma butyryl-cholinesterase activity on admission and at regular intervals during admission and clinical outcomes of cases admitted to the Toxicology Clinic of "Sf. Spiridon" Emergency Hospital Iasi, Romania between 1983 and 2013 were evaluated. **Results:** A total number of 606 patients were included in the study. The mean BuChE-activity level on admission was 1.54 ml NaOH N/100. A correlation between the amount of ingested organophosphates/carbamates (OPs/CMs) and low cholinesterase activity on admission was found. 66.66% of the patients were admitted to hospital within 8 hours after poisoning. The initial, daily and mean total atropine doses administrated were 9.65 mg, 10.51 mg and 69.39 mg, respectively. 67.16% of the investigated patients received Toxogonin for 6.41 days showing a slow increase in BuChE activity afterwards. The average number of hospital days was 11.22. The study revealed that complications occurred in patients with BuChE-activity levels below 1.4 mL NaOH N/100. A positive correlation between mortality rate (3.8% of patients) and the lowest BuChE-activity level on admission (0.89 mL NaOH N/100) was found. **Conclusions:** BuChE activity on admission and its level during hospital stay represent an important predictive factor for acute cholinesterase inhibitors poisoning. **Keywords:** BUTYRYL-CHOLINESTERASE, CHOLINESTERASE INHIBITORS POISONING, TOXICITY

Organophosphates (OPs) and carbamates (CMs) are toxic synthetic compounds that are used as: (a) insecticides, (b) chemical warfare agents, (c) therapeutic agents in veterinary and human medicine (1, 2, 3). Nowadays they are the most commonly used pesticides worldwide.

The World Health Organization (WHO) estimates that every year over 3 million people experience acute poisoning by OPs, with more than 200.000 deaths. OPs self-poisoning is more common than unintentional intoxication, which is very rare, especially in areas where WHO class I toxicity pesticides are used (4). Farmers and people employed in agriculture are considered a

high-risk group of accidental intoxication with OPs (5, 6, 7). There are reports indicating that in many rural areas of Asia, where farmers are constantly using toxic pesticides, OPs are frequently used in suicides (8).

Their primary mechanism of action is the inhibition of esterase enzymes, especially acetylcholinesterase and butyrylcholinesterase. These two enzymes are biomarkers of OPs and CMs systemic toxicity. Acetylcholinesterase inhibition results in accumulation of acetylcholine and overstimulation of both muscarinic and nicotinic receptors. Red-cell acetyl-cholinesterase inhibition is correlated with poisoning severity and can guide the oxime and atropine therapy. Acute butyryl-cholinesterase inhibition does not seem to cause clinical features and is not related to severity of poisoning. It can be used as a marker of exposure to OPs or CMs and for measuring cholinesterase-inhibiting compound elimination from the body. Many OPs pesticides are more potent inhibitors of butyrylcholinesterase than they are of acetylcholinesterase (9, 10).

The main goal of this study was to evaluate BuChE activity as a biomarker of acute OPs/CMs poisoning, in patients admitted to the Internal Medicine and Toxicology Clinic of “Sf. Spiridon” Emergency Hospital Iasi between 1983 and 2013.

MATERIAL AND METHODS

We conducted a descriptive retrospective clinical study on patients with OPs/CMs poisoning admitted to the Internal Medicine and Toxicology Department of the Iasi "Sf. Spiridon" Emergency Hospital aimed at evaluating the phenomenon of acute cholinesterase inhibitor poisoning over a period of 30 years.

Hospital records of patients diagnosed with acute accidental/voluntary OP or CM poisoning between the years 1983-2013 were reviewed.

The obtained data were used to create a complex and complete medical profile for each intoxicated patient.

A total of 53 parameters were assessed. The data on BuChE activity were evaluated by the analysis of following parameters: (a) BuChE-activity level on admission; (b) BuChE activity during hospital stay (c) time to serum cholinesterase return to normal physiological levels.

BuChE activity on admission was expressed as ml of NaOH N/100, not as mU/mL due to the fact that in most patients the Michel method for BuChE determination was used. Reference values were considered between 4-6 mL NaOH N/100. The others patients were assessed using the Ellman method; the obtained cholinesterase levels were expressed as mU/mL and then converted to mL NaOH N/100.

The experimental protocol of this investigation was implemented according to recommendations of the University Committee for Research and Ethical Issues, and to the guidelines stipulated in the EU Charter of Fundamental Rights, regarding clinical investigations on human subjects (10).

Statistical analysis of data was performed using SPSS for Windows version 19.0 and one-way ANOVA method, followed by Bonferroni post hoc test. Chi-square test was used for comparing means and variables and frequency analysis, considering the level of significance for p value less than 0.05.

RESULTS AND DISCUSSION

A total number of 606 patients were included, accounting for 11% of the total number of acute poisonings. The highest number of cholinesterase inhibitor poison-

ing cases was admitted in 1995 (44 cases).

BuChE activities on admission and during hospital stay were assessed using several parameters: (a) means of patient transportation to hospital (ambulance or means of transportation others than ambulance); (b) time interval between poisoning and hospital admission; (c) amount of ingested OPs; (d) age and sex; (e) clinical parameters; (f) treatment (initial, daily and total dose of atropine, Toxogonin® treatment); (g) time to return to normal BuChE levels; (h) course; (i) complications; (j) discharge status.

On admission most patients had a BuChE level around 1.5 mL NaOH N/100 (fig. 1).

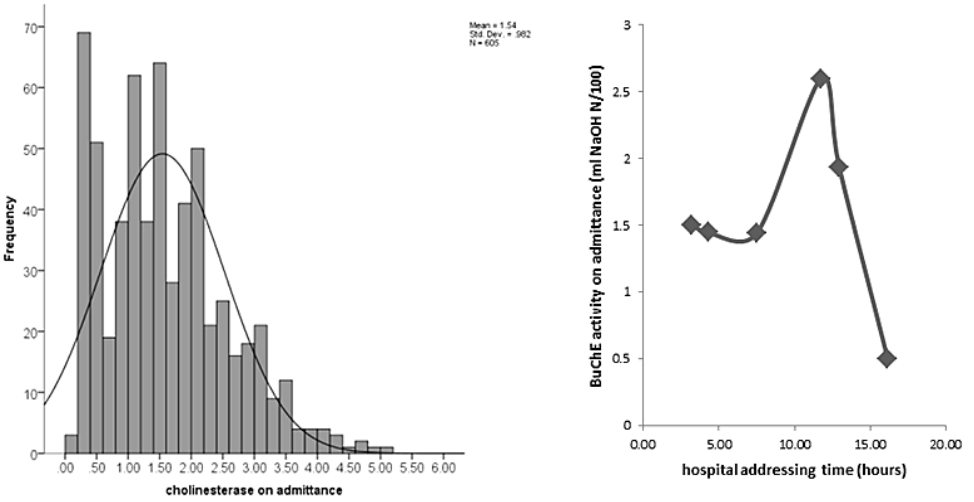

Fig. 1. Cholinesterase activity on admission. Correlations between butyrylcholinesterase activity on admission and hospital addressing time.

The estimated average time for admission to the emergency department after poisoning was 8.8 hours. 66.66% of the patients admitted to hospital within 8 hours after poisoning were using personal means of transportation and had an average serum BuChE level of 1.5 mL NaOH N/100. 6.72% of the patients admitted within 16 hours after poisoning were transported to hospital by ambulance and had an average serum BuChE level of 0.5 mL NaOH N/100 (fig. 1).

It is worth mentioning that patients using personal means of transportation reached the hospital in a shorter time frame than those that transported by the ambulance.

We found a correlation between the amount of ingested OPs/CMs and low cholinesterase activity on admission (p=0.002). More than half of the patients (58.74%) had ingested a small amount of OPs/CMs (average 69.19 mL). In this group, the cholinesterase activity level on admission was on average 1.44 mL NaOH N/100, with a slow increasing tendency. A rapid increase in cholinesterase activity was found in patients that ingested a higher amount of OPs/CMs (84.73 mL). In these patients, the cholinesterase activity on admission was 2.33 mL NaOH N/100 (fig. 1).

In patients older than 80 years, the average BuChE level was 0.22 mL NaOH

N/100. The highest average BuChE level recorded was 1.88 mL NaOH N/100 in patients aged 16 to 19 years.

There were no statistically significant differences (p=0.084) in average BuChE levels on admission between females and males.

The higher the average BuChE level on admission, the less complicated were the clinical manifestations of poisoning (p=0.000).

The initial, daily and total mean atropine doses administrated were 9.65 mg, 10.51 mg and 69.39 mg, respectively. Patients with average BuChE levels around 2.5 mL NaOH N/100 and 0.5 mL NaOH N/100 on admission were given a lower atropine dose. In patients with a plateau BuChE level on admission followed by an increase during hospital stay, the highest total atropine dose - 90.52 mg was administrated. The smallest total atropine dose was administrated in patients that had a dramatic increase in BuChE activity (fig. 2).
The initial and daily atropine doses were almost similar. There were no significant differences between initial and daily doses of atropine when compared with BuChE activity on admission. One significant difference was found between the total dose of atropine and BuChE activity on admission: the lower BuChE activity on admission, the higher the atropine dose administrated to the patient.

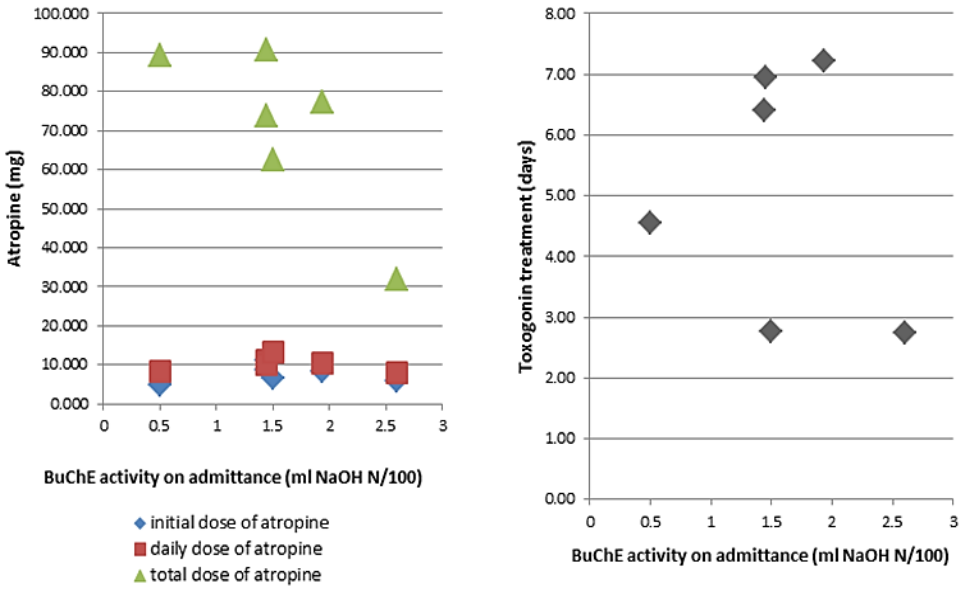

Fig. 2. Correlations between butyrylcholinesterase activity on admission, atropine and Toxogonin therapy.

The mean duration of Toxogonin treatment was 5.74 days. 67.16% of the patients (BuChE on admission 1.44 mL NaOH N/100) received Toxogonin for 6.41 days and showed a slow increase in BuChE activity afterwards. The longest duration of

Toxogonin treatment (7.23 days) was in patients with a decreasing BuChE tendency after admission, followed by an increase in BuChE activity. The shortest Toxogonin treatment (2.74 days) was given to the patients who had a dramatic increase in BuChE activity after admission (fig. 2).

No correlation was found between the total number of Toxogonin treatment days and the initial BuChE level on admission. There was a strong correlation between the total number of Toxogonin treatment days and the further BuChE activity during hospital stay (p=0.000).

Of all patients, 9.75% received exogenous cholinesterase. There were no statistically significant differences regarding BuChE initial activity between these patients and the patients who did not receive exogenous cholinesterase (p=0.361).

The following correlations were found: BuChE activity increased in patients with the highest BuChE levels on admission; BuChE activity was oscillating in patients with the lowest BuChE levels on admission; the return to normal of serum cholinesterase activity was positively correlated with the mean initial BuChE level on admission.

In most of the patients (67.73%) cholinesterase activity returned to normal within 6-7 days after admission, following an ascending slope (fig. 3). In patients with the lowest initial BuChE level on admission (0.5 mL NaOH N/100) cholinesterase activity was oscillating, described by alternated ascending and descending slopes, and was not normal at the time of the discharge from hospital. In patients with the highest mean BuChE level on admission (2.59 mL NaOH N/100) cholinesterase activity had rapidly increased, returning to normal physiological values 3 days after admission (fig. 3, 4).

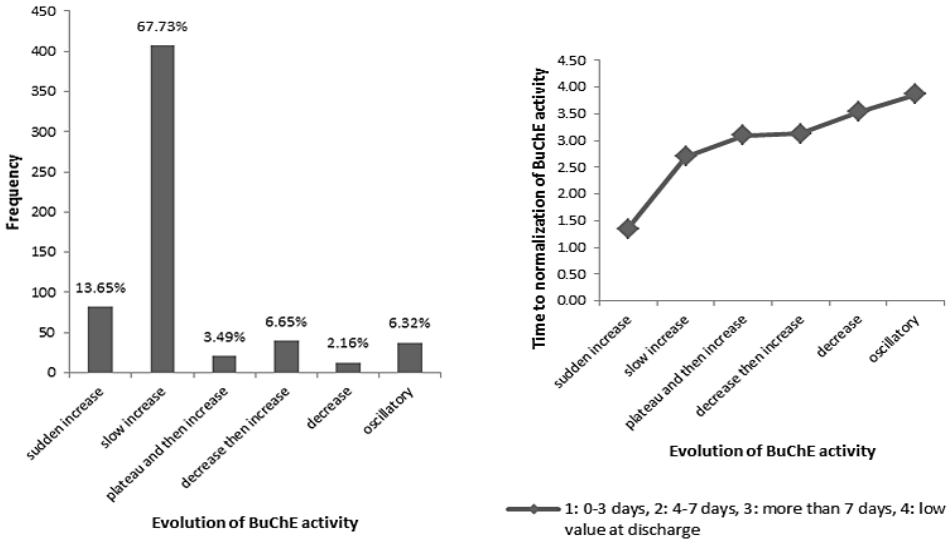

Fig. 3. Correlations between the course of butyrylcholinesterase activity, frequency and time to normalization.

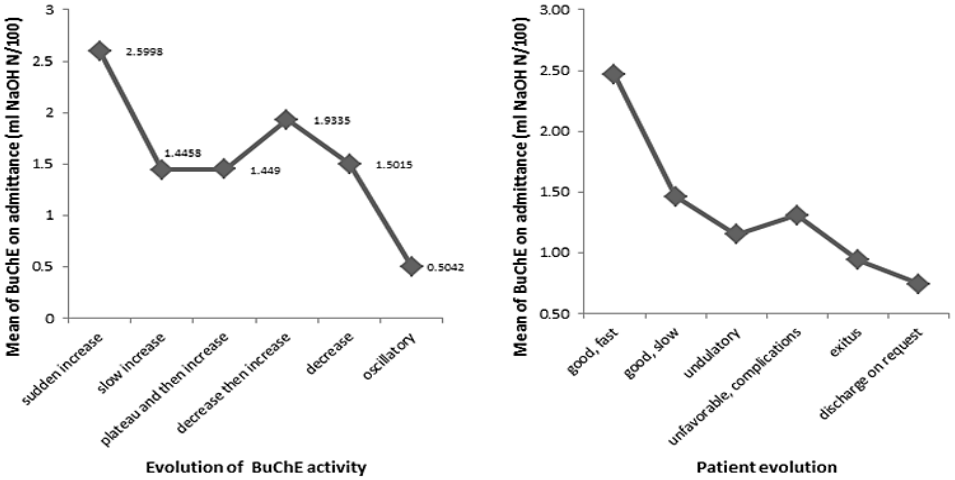

Fig. 4. Correlations between mean BuChE activity on admission, its dynamics and patient course

The higher the BuChE on admission, the better the patient clinical course - p=0.000.

Of the total number of patients, in 67.73%, with a slow increasing tendency for BuChE, the average length of hospital stay of 11.65 days. In patients with a dramatic BuChE increasing tendency, the average length of the hospital stay was 6.7 days. The highest average length of stay was 13.95 days and was recorded in patients with a plateau-like BuChE activity followed by an increase in activity – mean BuChE level on admission 1.44 mL NaOH N/100. The mean length of hospital stay was positively correlated with BuChE course and its normalization time.

Our investigation demonstrated a higher incidence of complications in patients with BuChE levels below 1.4 mL NaOH N/100. In patients with BuChE levels above 1.66 mL NaOH N/100 (73% of patients) no complications were present.

The most frequently recorded complications were acute pulmonary edema (10.6% of cases), in patients with of 1.29 mL NaOH N/100 and toxic myocarditis (3.2% of cases), in patients with a mean BuChE activity of 1.38 mL NaOH N/100 on admission (Fig. 5). A BuChE level of 0.85 mL NaOH N/100 on admission was associated with such complications as: respiratory problems (1.3% of cases) and cardiac rhythm disturbances (0.7% of cases).

Our results indicate a positive correlation (p=0.072) between the presence of both cardiac arrest (3% of cases) and sudden death (0.3% of cases), and the mean level of BuChE activity (1.2 mL NaOH N/100).

A positive correlation was also found between mortality (3.8% of patients) and the lowest average BuChE activity on admission - 0.89 mL NaOH N/100.

Of the total number of patients, 80% were discharged at the recommendation of the treating physician (mean BuChE activity level of 1.63 mL NaOH N/100 on admission), while 10.41% on request (1.13 mL NaOH N/100) (fig. 5).

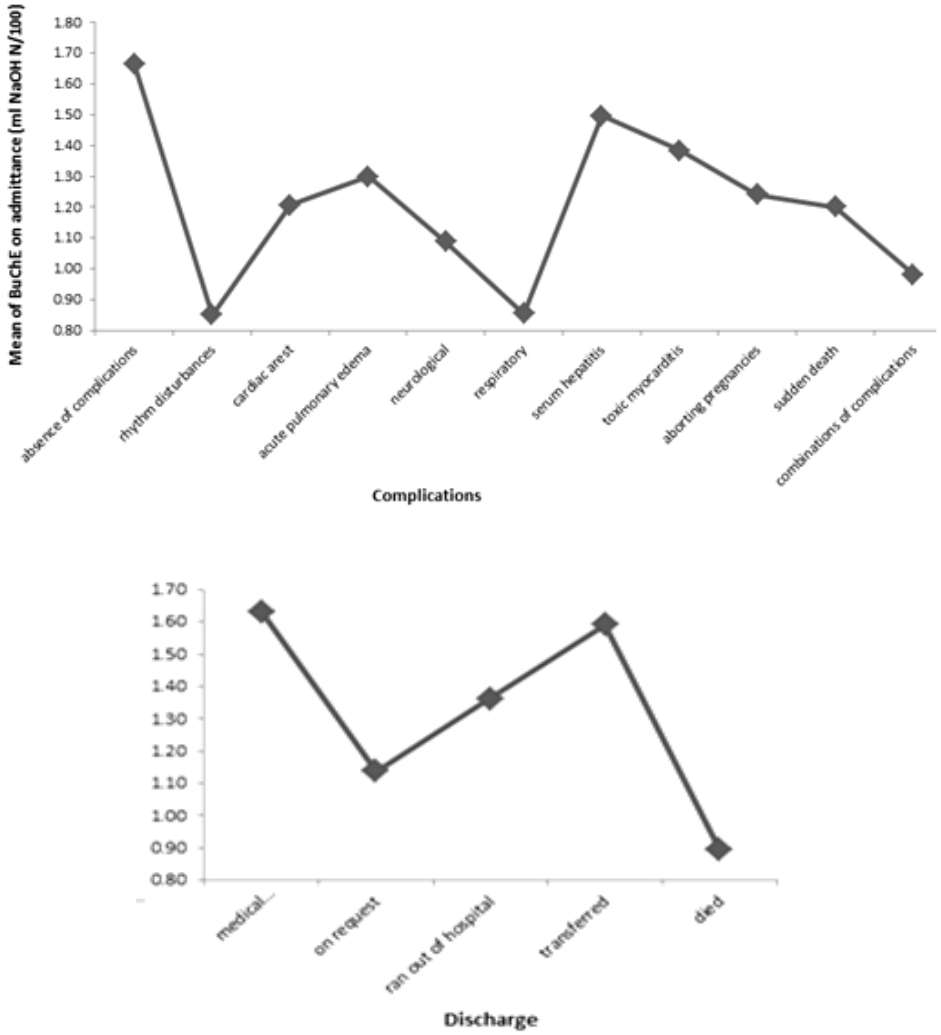

Fig.5. Correlations between **complications**, **discharge** status and butyrylcholinesterase activity on admission

CONCLUSIONS

In our study BuChE activity on admission and its course during hospital stay represents an important prognostic factor for cholinesterase inhibitors acute poisoning. The decrease of BuChE activity was positively correlated with the degree of poisoning. A tendency of BuChE activity to increase in patients with high BuChE levels and an oscillating course in patients with low BuChE activity level on admission were found. Complications were reported in patients with BuChE levels below 1.4 mL NaOH N/100, but not in patients with BuChE levels above 1.66 mL NaOH N/100.The incidence of mortality was correlated with low mean BuChE levels on admission.

NEWS

BACTERIAL INFECTION - SIDE EFFECTS OF COSMETIC TREATMENT

The lip augmentation and wrinkle smoothening are very commune, but the cosmetic treatment which consists in injection of soft tissue fillers can induce tender subcutaneous lumps and lesions difficult to treat. A recent study published in the journal *Pathogens and Disease*, showed that side effects of filler treatment are caused by bacterial infection. Using a mouse model, the researchers evaluated capacity of fillers for sustaining bacterial infections and the possible treatment strategies. Three type of gel contaminated with *Pseudomonas aeruginosa*, *Staphylococcus epidermidis*, and *Propionibacterium acnes* were injected in a mouse model. The results showed that the permanent gel was able to sustain bacterial infection more than the semi-permanent gel. Temporary gel did not cause infection. Also, the study revealed that antibiotic treatment become inefficient if bacteria have formed a biofilm. This research emphasizes importance of antibiotics injection together with the filler itself, for prevent bacterial complications induced by cosmetic treatment (Alhede M, Er Ö, Eickhardt S et al. Bacterial biofilm formation and treatment in soft tissue fillers. *Pathogens and Disease*. 2014; DOI: 10.1111/2049-632X.12139).

SURGICAL TREATMENT OF CHRONIC COLOSTASIS IN CHILDREN: A TEN YEAR EXPERIENCE (Abstract) **Objective:** To analyze our ten year experience of surgical treatment of children with chronic colonostasis of different origin.**Material and methods:** The study covers 353 children aged from 1 day to 17 years with colonic stasis who undergo treatment at the Department of Children's Surgery, Bukovinian State Medical University, Cernăuţi, Ukraine. Study design included case history, physical examination, routine clinical and biochemical laboratory tests, endoscopy (sigmoidoscopy, colonoscopy), X-ray (irrigoscopy, irrigography, other radiopaque techniques) methods, and sphincterometry. **Results.** Non-surgical treatment was effective in 261 (73.94 %) patients. The group of the operated patients consisted of 92 (26.06 %) children. The outcome of surgical treatment of Hirschsprung's disease (49 children), dolichosigmoid (29 children), Payr's disease (12 children), and Chilaiditi syndrome in all cases is considered to be satisfactory.The optimal methods of surgical operations are offered according to pathology of colon. **Conclusions:** One-step Soave-Boley operation is considered to be the method of choice for rectal and rectosigmoid forms of Hirschprung's disease. Transversal colon resection and phrenico-colic ligament dissection in Payr's disease, hepatopexia and right colon fixation in Chilaiditi syndrome are effective treatment approaches. **Keywords:** SURGERY, CHILDREN, CONSTIPATION.

Chronic constipation in children is greatly under evaluated problem since this disease affects over 15% of the entire population. Obstipation syndrome appears at birth or early childhood in about 30% of patients (1). Disorders of transit through the colon may be due to (2) anatomical features (elongation, drooping, creases, looping, abnormal mobility of the various parts, abnormal intramural nerve plexus) and functional factors (nutritional, dyskinetic, reflectory, intoxication).

However, underlying mechanisms of pathogenesis are not sufficiently clear. It may be determined by specific polymorphism of candidate gene (3), or similarly to other diseases by combination of different candidate genes polymorphisms attributing into increased risk by means of changed metabolism and regulation, thus causing appropriate switch in genetically determined therapies (4).

However, even introduction of modern sophisticated research techniques (5) did

not clarify important questions related to the problem.

Organic pathology in childhood requires extremely traumatic and difficult colonic surgical interventions.

Tactical and technical errors in performance of surgical treatment of colonostasis in children lead to the formation of a huge number of complications, disability, and social disadaptation (6). The aim of this study is to analyze our ten-year experience of surgical treatment of children with chronic colonostasis of different origin.

MATERIAL AND METHODS

This study conforms to international bioethical standards (European Convention on Human Rights and Biomedicine, the Declaration of Helsinki of the World Medical Association on ethical principles of scientific medical research involving human subjects, GCP, EUC directive #609, etc.) and approved by Commission for Bioethics in Research of the Bukovinian State Medical University, Ukraine. All patients' representatives signed written permissions and obtained full information about the study prior to participation.

The study covers 353 children aged from 1 day to 17 years with colonic stasis who undergo treatment at the Department of Children's Surgery, Bukovinian State Medical University, Cernăuţi, Ukraine (tab. I).

TABLE I

Distribution of children with colonostasis according to the etiology of disease

Pathology	Number of children	Number of operated children
Hirschprung's disease	49 (13.88%)	49 (100%)
Dolichosigmoid (isolated)	144 (40.79%)	15 (10.42%)
Dolichosigmoid+ high position of the left colonic flexure	36 (10.20%)	14 (38.89%)
Payr's disease	29 (8.22%)	12 (41.38%)
Chilaiditi syndrome	2 (0.57%)	2 (100%)
Spastic colitis	11 (3.12)	0
Neural disorders	7 (1.98%)	0
Functional disorders	75 (21.25%)	0
Total	353 (100%)	92 (26.06%)

Study design included case history, physical examination, routine clinical and biochemical laboratory tests, endoscopy (sigmoidoscopy, colonoscopy), X-ray (irrigoscopy, irrigography, other radiopaque techniques) methods and sphinctero-metry.

Hirschprung's disease diagnosis was based on the presence of areas of narrowing in the distal colon with proximal funnel-like expansion at X-ray pictures, absence or abrupt decrease of the contrast passage of in expended parts of the large intestine, anal sphincter hypertonia. Subtotal form of agangliosis was observed in seven children, rectosigmoid in 29, and rectal in 13. The diagnosis was confirmed with a rectal suction biopsy, which presented the absence of ganglion cells and the presence of hypertrophic nerve trunks (7).

Dolichosigmoid diagnosis was based on

the analysis of the sigmoid colon by following criteria: length, width, additional loops of colon, presence/retention of radiopaque mixture in the sigmoid colon and proximal colon after bowel movements and defecation. We clinically distinguished dolichosigmoid with violated evacuation function and without it. The presence of left colonic flexure high position was observed in 36 children and isolated dolichosigmoid in 144 (fig. 1).

Fig. 1. Irrigogramm, patient P., 12 years old, prior to defecation. Dolichosigmoid with left colonic flexure high position (2) compared to right flexure (1)

RESULTS AND DISCUSSION

In 12 patients with Hirschprung's disease, the first stage of surgical treatment was colostomy. The major indications for the *anus praeter naturalis* for Hirschprung's disease were: colon perforation (1 patient); transversal torsion (1 patient), decompensated enterocolitis and colic dilatation with severe fecal intoxication (three children), acute form of Hirschprung's disease (4 patients), ineffectiveness of conservative treatment (3 children). In three patients in the neonatal period,we formed suspended transversostoma, as a first step before performing De la Torre transverso-endorectal pull-through (8). In ninechildren,anus *praeternaturalis* was applied on the transition agangliosis area.

In subtotal agangliosis form of Hirschsprung's disease, colon pull-through maneuver in the left side sinus performed in 3 patients, the bowel pull-through in the right mesenteric sinus holding it in front of the terminal ileum performed in two children, and pull-through of the ascending colon with 180^0 turn performed in two patients.

In 10 children with rectosigmoid form of Hirschprung's disease and in 5 with rectal form modified Soave operation wasperformed. In 17 children with rectosigmoid form and in 7 with rectal form we performed Soave-Boley procedure. In two patients with rectosigmoid form and in one with rectal form a three stage (stage 1– transversostomy, stage 2 – transanal endorectal pull-through maneuver, stage 3– transversostomy closure) endo-rectal pull-through surgery (tab. II).

According to the type of surgery, all patients with dolichosigmoid were divided into two groups: group 1 with traditional sigmoid resection and group 2 with formation of superior sigmoid ligament using our technique (tab. III).

The technique of surgery was as follows. We performed sinistral transrectal laparotomy. Mobilization of the sigmoid colon with dissection of its lateral posterior peritoneal fold. Distal portion of colon was pulled up to determine hypertrophyand level of resection, applying "marking sutures" so that the no prolapsed bowel is left

in pelvis. Sigmoid crossed at the level of the distal portion, 3-4 cm above the promontory and the proximal part of the colon was resected in strained position so that it was left enough for application of anastomosis with already crossed bowel.

TABLE II

Distribution of children with the Hirschprung's disease by type of surgery

Operation	Hirschprung's disease forms			Total
	Subtotal	Rectosigmoid	Rectal	
Pull-through maneuver in the left side sinus	3 (42.9%)	–	–	3 (6.1%)
Pull-through maneuver in the right side sinus	2 (28.6%)	–	–	2 (4.1%)
Pull-through of the ascending colon with 180° turn	2 (28.6%)	–	–	2 (4.1%)
Modified Soave technique	–	10 (34.5%)	5 (38.5%)	15 (30.6%)
Soave-Boley procedure	–	17 (58.6%)	7 (53.9%)	24 (49.0%)
Transanal endorectal pull-through	–	2 (6.9%)	1 (7.7%)	3 (6.1%)
Total	7	29	13	49

TABLE III

Distribution of children operated for dolichosigmoid depending on type of surgery

Technique	Type of dolichosigmoid		Total
	Isolated dolichosigmoid (1 group)	Dolichosigmoid + high position of the left colonic flexure (2 group)	
Sigmoid resection	8 (53.3%)	8 (57.1%)	16 (55.2%)
Sigmoid resection + formation of superior sigmoid ligament	7 (46.65)	6 (42.9%)	13 (44.8%)
Total	15	14	29

End-to-end anastomosis with interrupted inverted sero-muscular sutures was imposed. The upper sigmoid ligament was formed by suturing of section of colon above the anastomosis to the parietal peritoneum by interrupted sutures (fig. 2).

In case of high left colonic flexure and dolichosigm we dissected phrenicocolicum ligament.

Histological examination showed sclerosis of the *lamina propria* of the mucosa. In submucosal tissue a process of sclerosis combined with fatty degeneration, hypertrophy of muscle fibers and atrophic processes (myocyte vacuolization), sclerotic changes of serosa and mesenteric tissues.

After traditional sigmoid resection periodic constipation after surgery was observed in 18.75%, abdominal pain in 37.5%, partial incontinence in 60%. After addition of the upper sigmoid ligament formation during surgery, constipation was absent, abdominal pain persisted in 14.29%, partial incontinence in 16.67%.

Surgery for Payr's disease included upper midline laparotomy, division of adhesions in the region of the splenic flexure and dissection of the phrenico-colic ligament. Excessive transversal was mobilized between Hirsch's and Payr-Strauss' sphincters. Transversal colon resection with restoration of passage by imposing end-to-end anastomosis was performed with interrupted inline inverting sutures (PDS 4/0).

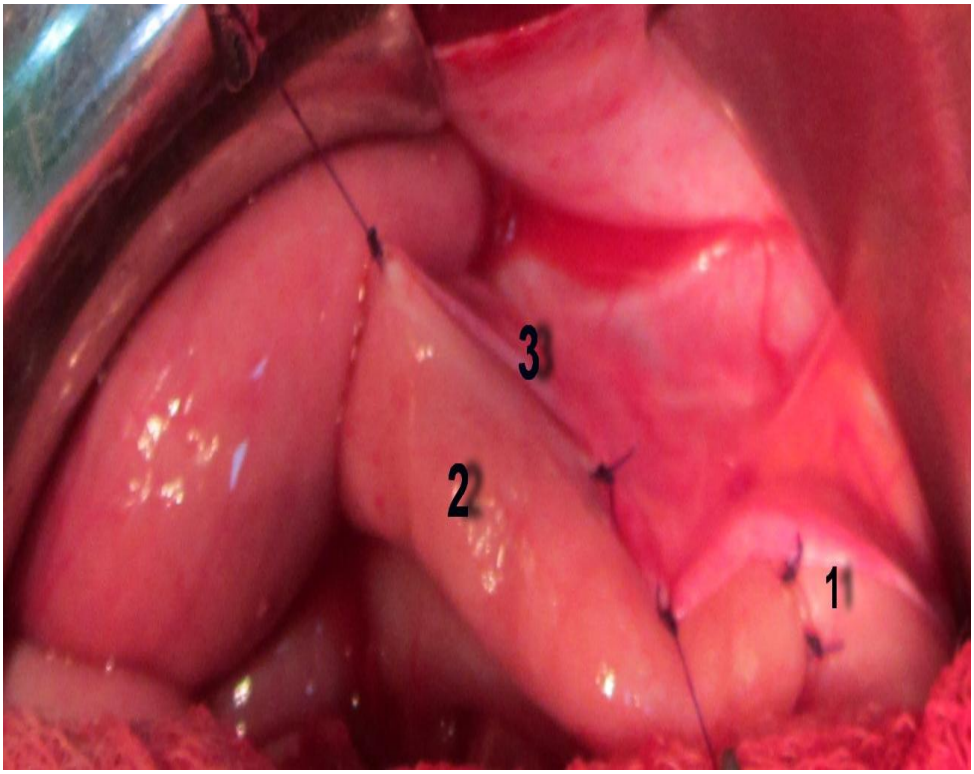

Fig. 2. Resection of the sigmoid colon (2). Intestino-colic end-to-end anastomosis (1). Formation of the upper sigmoid ligament (3)

Histological examination of the resected transversal colon showed no changes. However, there was sclerosis of the lamina *propria* of the mucosa; in submucosal tissue sclerotic process combined with fatty degeneration. There was hypertrophy of muscle fibers, and in some cases (5 children) atrophic processes (vacuolization of myocytes), indicating progression of the disease;rough connective tissue between muscle fibers around the vascular cells and nerve plexus. In several cases (four children) observed serosa and mesenterial tissue sclerosis.

In patients with Chilaiditi syndrome performed right lobular lateral hepatopexia by corrugating falciform and triangular ligaments with their fixation diaphragm; colofixation of right colonic flexure to the parietal peritoneum.

The quality of life of children after surgery for Payr's disease and Chilaiditi syndrome, calculated in SF-36 was evaluated as satisfactory with elimination of pain and

chronic constipation.

CONCLUSIONS

The optimal method for surgical treatment of rectal and rectosigmoid forms of Hirschprung's disease in children is the one-step Soave-Boley operation.

The most rational way to restore the integrity of the intestinal tract after subtotal colon resection is colorectal anastomosis on the right or left mesenterial sinus (depending on the length of the segment).

Sigmoid colon resection with formation of the upper sigmoid ligament can be an operation of choice for surgical treatment of chronic colostasis under dolichosigmoid in children.

Resection of colon *transversum* and phrenico-colic ligament dissection, in Payr's disease, hepatopexia,and right colon fixation in Chilaiditi syndrome are effective treatment methods for these diseases in children.

AMIODARONE-INDUCED THYROID DYSFUNCTION – CLINICAL PICTURE. STUDY ON 215 CASES

Cristina Preda[1], Ana Clara Aprotosoaie[3], A. Petris[2], Irina Iuliana Costache[2]

AMIODARONE-INDUCED THYROID DYSFUNCTION – CLINICAL PICTURE STUDY ON 215 CASES **(**Abstract): **Aim**: The purpose of this study was to investigate the prevalence and the clinical-evolutionary implications of thyroid damage in patients treated with amiodarone in the Cardiology Clinic of the "Sf. Spiridon" University Hospital of Iasi. **Material and Methods:** The study included a group of 215 patients, 90 men and 125 women with ages between 35 and 87, hospitalized in the Cardiology Clinic between 2004 and 2014, who received amiodarone treatment, in most cases for the prophylaxis of various arrhythmias, both supra-ventricular and ventricular. **Results:** In 27.80% of the patients, the assessment of the thyroid function was imposed by the appearance of the clinical picture characteristic for hypo- and hyperthyroidism, and for 72.19% it was carried out as a routine examination. Amiodarone-induced hypothyroidism was clinically diagnosed in 20.85% of the patients. Hyperthyroidism occurring during treatment with Cordarone was found in 6.95% of the patients. The confirmation of the diagnosis of amiodarone-induced thyroid dysfunction was based on hormonal dosages (TSH, FT4 and even FT3 in some cases), on the endocrinological clinical consultation and on the imaging study – i.e. thyroid echography. **Conclusions:** Amiodarone-induced thyroid dysfunction is relatively rare compared to the number of patients treated with this anti-arrhythmic drug (27.8%) from the group under study. Thyroid dysfunction, regardless of the type (with hypo or hyper-function), represents a negative element in the evolution of patients with pre-existing heart diseases, not only by aggravating the clinical picture of the basic illness, but also by the necessity of permanently reviewing the therapeutic scheme imposed also by the association of thyroid dysfunction medication, according to case. **Keywords:** AMIODARONE, HYPOTHYROIDISM, HYPERTHYROIDISM.

Discovered in 1961 by Tondeur and Binon, amiodarone has been widely used especially in Europe, initially as anti-anginal preparation and later on as anti-arrhythmic, proving its effectiveness in the treatment of both atrial and ventricular arrhythmias with a malignant potential, being considered one the most effective anti-arrhythmic agents in preventing sudden arrhythmic cardiac death (1, 9). In 1985, amiodarone was approved by the FDA (*Food and Drug Administration*) for the treatment of atrial fibrillation and the prevention of recurrent ventricular tachy-

cardia. Despite this beneficial activity the prescription of amiodarone started to be limited due to the occurrence of serious side effects, some even disastrous, which were associated with the chronic use of the drug (2, 6, 8). Among these, the effects on the thyroid function raise the biggest issues for both patient and the physician; often it is necessary to reassess the therapeutic scheme because of the need to treat the newly occurred thyroid dysfunction. Thyroid abnormalities have been observed in 14-18% of the patients that received the minimum dose of amiodarone (8). The effects on the thyroid are variable:

- subclinical impairment, i.e. abnormal thyroid function detected only through regular laboratory tests (TSH, FT4, FT3) in the absence of any clinical manifestations (5, 6).

- clinically manifested thyroid dysfunction: amiodarone-induced thyrotoxicosis or hypothyroidism. Both can occur either on a previously normal thyroid gland or in the context of a pre-existing thyroid impairment, which they may worsen (3, 4, 6, 7, 8, 9).

The mechanisms of amiodarone activity on the thyroid are particularly complex: amiodarone inhibits the activity of deiodinase enzyme and thereby it decreases the peripheral conversion of thyroid hormones. It also decreases their renal elimination, increases T4, decreases T3 by about 25% and inhibits the entry of T4 and T3 in the peripheral tissues. (8). Amiodarone together with its metabolite, also has a direct cytotoxic effect on the thyroid follicular cells, the result being a destructive thyroiditis. It acts as a competitive antagonist of T3 at the heart level (3, 4, 7, 8, 9).

Amiodarone-induced thyroid impairment can resemble the clinical and biochemical picture of either hypothyroidism or hyperthyroidism. Amiodarone-induced hyperthyroidism may be of two types: *Type 1* - due to excess iodine in amiodarone, which causes excessive synthesis of thyroid hormones; it usually occurs in subjects with prior thyroid impairment (subclinical or clinical) and *Type 2* – it appears as an inflammatory process followed by the destruction in those with previously normal thyroid. The latter type is far more serious and it requires an urgent specific therapeutic protocol, which also involves the administration of glucocorticoids. Combined forms of thyroid impairment are rare (6, 8, 9). This study aimed to investigate the prevalence and the clinical-evolutionary implications of thyroid impairment in patients treated with amiodarone hospitalized in the Cardiology Clinic of the "St. Spiridon" University Hospital of Iaşi.

MATERIAL AND METHODS

The study included a group of 215 patients hospitalized in the Cardiology Clinic between 2004 and 2014, who received amiodarone treatment, in most cases for the prophylaxis of various arrhythmias, both supraventricular and ventricular. The group included 90 men and 125 women aged between 35 and 87. Patients were examined clinically and paraclinically (12-lead electrocardiogram, 2D echocardiography, M mode and Doppler, chest radiography, and laboratory data common in patients with heart disease: renal function and electrolytes, liver function, myocardial cytolysis enzymes). Since patients were going to receive amiodarone in the treatment scheme, the thyroid function was investigated for all of them, by routine hormone dosing (TSH, FT4, FT3) prior to the beginning of the treatment.

The basic pathology of the patients from the group was represented by the following conditions:

- acute viral myocarditis;
- acute myocardial infarction complicated by supraventricular arrhythmias and ventricular ESV and ventricular tachycardia;
- other forms of ischemic cardiopathy;
- ischemic dilatative and toxic (ethanolic) cardiomyopathy;
- HTA; on the background of this disease, the patients had different atrial arrhythmias (ESA, FA, atrial flutter) and ventricular arrhythmias (ESV), which were considered the expression of hypertensive cardiopathy;
- amiodarone administration pre-and post cardioversion.

RESULTS AND DISCUSSION

The indications for amiodarone administration in the study group were:

- controlling atrial and ventricular arrhythmias in the absence of or after the failure of other therapeutic alternatives;
- preparing for electrical cardioversion in patients with recent atrial fibrillation (onset under 1 year), with clear indication of cardioversion;
- the prophylaxis of atrial fibrillation recurrence after obtaining sinus rhythm;
- the prophylaxis and treatment of malignant ventricular rhythm disturbances occurred on the background of the coronary ischemic disease (i.e. IMA or other clinical forms of chronic ischemic cardiomyopathy);
- the prevention and treatment of severe ventricular rhythm disturbances occurred in the evolution of patients with dilative cardiomyopathy, having various aetiologies (ischemic, alcoholic, acute viral post myocarditis).

All patients in the group had their thyroid function investigated prior to the administration of amiodarone through TSH, FT4 and FT3 dosing, and it was within normal limits. The posology for amiodarone was, in most cases, as load - 800-1200 mg/day for 7-10 days, followed then by the maintenance dose 200 mg/day, 5-7 days/week (1 - 1.4 g/week). The duration of the treatment up to the moment of being included in the study (considered to be the moment that thyroid damage was discovered) was between 6 months and 8 years. The evaluation of the thyroid function, after starting the treatment, was made in 187 patients from the group (86.97%). In 52 patients (27.80%), the evaluation of the thyroid function was imposed by the appearance of the clinical picture characteristic for hypo- and hyperthyroidism; in the remaining 135 (72.19%) a routine examination was carried out. Amiodarone-induced hypothyroidism was clinically diagnosed in 39 patients (20.85%), of whom 13 were women and 26 men. Clinical elements suggestive for the hypothyroidism diagnosis were: somnolence, carotenoderma, excessive bradycardia, important physical asthenia and skin infiltration. All cases were confirmed through elevated TSH values and low FT4 values.

Hyperthyroidism occurring during treatment with Cordarone has been encountered in 13 patients (6.95%), 10 men and 3 women. Hyperthyroidism apparition was suggested by the following signs and symptoms (classified as the hyperkinetic syndrome): sweating, tremor, the aggravation of a pre-existing atrial fibrillation by increasing the ventricular frequency that became refractory to all antiarrhythmic therapy, unexplainable weight loss and tachycardia. In 11 cases there was a wors-

ening of the clinical picture of cardiac insufficiency. In all cases of hyperthyroidism, TSH values were lowered with normal or increased FT4. The confirmation of the amiodarone-induced thyroid dysfunction diagnosis of required collaboration with the endocrinologist, and it followed these steps:

1. Laboratory studies – i.e. TSH, FT4 and FT3 dosing in some situations. In case of amiodarone-induced hypothyroidism, laboratory data have objectified increased levels of TSH with low levels of free FT4 in all patients. Serum thyroglobulin was dosed to a limited number of patients and it had high values;

Patients with amiodarone-induced hyperthyroidism had high levels of free FT3 and FT4, and low, or even undetectable, levels of TSH;

2. Endocrinologic clinical examination;

3. Imaging studies – i.e. thyroid echography which, only in 5 patients with amiodarone-induced hypothyroidism, proved the enlargement of the thyroid and the nodular structure with hypoechogenic areas (partially orienting towards type 1 of amiodarone-induced thyroid dysfunction). In the remaining patients, thyroid echography was normal.

The current study revealed the following:

- None of the patients in the study presented clinically obvious thyroid impairment prior to the initiation of the amiodarone therapy;

- The occurrence of thyroid dysfunction induced by amiodarone did not correlate with the underlying heart pathology or the duration of the treatment, nor with other major cardiovascular risk factors. Some correlation was observed in the female group between hypothyroidism and obesity (85% of the women who developed amiodarone - induced hypothyroidisms were previously obese). The clinical picture corresponding to thyroid dysfunction had as a particular feature, according to the case, only the association with the signs of basic heart disease;

- The period of time between the initiation of the amiodarone treatment and the occurrence of clinical signs of thyroid dysfunction, was highly variable, i.e. between 6 months and 8 years. Also, no correlation could be established between the type of thyroid dysfunction (with hypo or hyperfunction) and the length of the treatment with amiodarone. In general, in female patients, thyroid dysfunction was diagnosed earlier because they came more often to the examination;

- There was no correlation between the administered amiodarone maintenance dose and the occurrence of a certain type of thyroid dysfunction;

- Amiodarone-induced hyperthyroidism was more common in male patients, on whom it caused an extremely unfavourable evolution and a prognosis: fibrillation and atrial flutter with rapid ventricular pace (over 150/min) resistant to antiarrhythmic therapy, and fatalities due to the worsening of the cardiac failure phenomena evolving up to cardiogenic shock and refractory acute renal failure.

Patients diagnosed with amiodarone-induced hypothyroidism had a somewhat favourable evolution after beginning the treatment with replacement hormones, i.e. alleviation of the clinical picture together with the correction of the thyroid hormone levels. Most patients who developed hypothyroidism showed an excessive bradycardia (i.e. 40-45/minute ventricular frequencies), symptoms (dizziness), which made

them come to for examination.

CONCLUSIONS

Amiodarone-induced thyroid dysfunction is relatively rare compared to the high number of patients treated with this antiarrhythmic (27.8% of the studied group). Amiodarone-induced hypothyroidism is usually less obvious, in terms of the clinical picture, while the amiodarone-induced hyperthyroidism has a severe clinical picture by worsening the phenomena of cardiac insufficiency, by maintaining an elevated heart rate, generally resistant to antiarrhythmic drugs; some cases can be fatal especially when they occur on a severe basic cardiac pathology. Thyroid dysfunction, regardless of the type (with hypo- or hyper-function), represents a negative element in the evolution of the patients with pre-existing cardiac pathology, not only through the worsening of the clinical picture of the underlying disease, but also through the need to permanently review the therapeutic scheme also imposed by the association of the medication of the thyroid dysfunction, according to case.

MASSIVE PERICARDIAL EFFUSION ASSOCIATED WITH HYPOTIROIDISM (Abstract): The diagnosis of hypothyroidism is difficult because hypothyroidism in adults and especially the elderly, classic, has an insidious onset with a range of nonspecific symptoms which may delay diagnosis for months or even years. Old age seems to represent trigger factor for autoimmune diseases, including hypothyroidism. Clinical features in hypothyroidism, such as weight gain, fatigue, intolerance of the cold, constipation, dry skin, edema and muscle weakness, and decreased osteo-tendinous reflexes are usually subtle and can be overlooked. Thyroid dysfunction may be associated with a negative impact on the cardiovascular system. Pericardial, pleural and peritoneal effusions are common findings in hypothyroidism. This case report represents a typical primary hypothyroidism (autoimmune) and shows the clinical features of this disease. Basically we talked about a severe myxedema with the involvement of internal organs in an elderly woman and the euthyroidism restoration, under thyroid replacement therapy, was correlated with the clinical improvement and cardiovascular and neurological status, with radiographic remission and regression to extinction of pericardial effusion at repeated echocardiographic evaluations. **Keywords:** AUTOIMMUNE THYROIDITIS, HYPOTHYROIDISM, PERICARDIAL EFFUSION, LEVOTHYROXINE.

Thyroid dysfunction may be associated with a negative impact on the cardiovascular system. The prevalence of hypothyroidism increases with age (1,4), especially in women (2,3) and is often difficult to diagnose clinically in elderly patients (1,5). Old age seems to represent a trigger factor for autoimmune diseases, including hypothyroidism (3).

Incidence of pericardial effusion in hypothyroidism is related to the severity and duration of disease, beeing reported to be in approximately one-third of the cases, as low as 3% in the early mild stage and as high as 80% when myxedema is present (6).

Pericardial, pleural and peritoneal effusions are common findings in hypothyroidism. A few cases have been reported in which pericardial fluid evolved in to tamponade. A variety of conditions can cause pericardial effusion. Early recognition of etiologic factors is important to improve outcome and avoid unnecessary invasive investigations. Once a diagnosis set, pericardial effusion slowly regresses and eventually disappears after several months of

replacement therapy. We here present the case of a patient with massive pericardial effusion associated with hypothyroidism, which responded to levothyroxine replacement therapy after 6 months.

CASE REPORT

A 84-year-old woman presented at the emergency department of our hospital, with profound dyspnea, pronounced asthenia, somnolence, vertigo, paresthesia, symptoms emphasized about 2 weeks prior hospitalization, in terms of ambulatory detection by echocardiographic exploration of an important pericardial effusion (fig. 1).

The patient has husky voice, slow speech, and periods of disorientation in time and space and visual hallucinations. Physical examination revealed cool and dry skin, eyelid edema and edema of the extremities, faint heart sounds with a heart rate of 54 beats / minute, TA= 125/88 mmHg, bilateral basal crackles and reduced vesicular murmur, with a respiratory rate of 20 breaths / min and a temperature of 35.4 °C, coprostasis. Neurological examination revealed delayed deep tendon reflexes, dysdiadochokinesia, depressive mood.

Fig. 1. Ultrasound 2D parasternal long axis section, the objectification of pericardial fluid disposed in the posterior wall of the left ventricle in diastole of 18.31 mm.

Laboratory tests revealed blood count and C-reactive protein (CRP) values within normal limits, hypercholesterolemia 373 mg/dl, an LDL-cholesterol of 250 mg/dl, HDL cholesterol 47 mg/dl and triglycerides 193 mg/dl.

An electrocardiogram revealed sinus bradycardia, with a low P wave and QRS complexes and first degree atrioventricular block (PQ was 0.24 sec). Chest radiograph identified cardiac enlargement and bilateral pleural effusion.

The echocardiogram revealed massive pericardial effusion, disposed circumferentially with fibrin deposits in fluid or on epicardial surface, with measurement of the

pericardium separation foils, with a maximum of 28 mm and an approximate estimated liquid volume 600 ml, without signs of tamponade (fig. 1, 2, 3).

Fig. 2. Ultrasound 2D parasternal short shaft section outlining the pericardial fluid in large quantities ordered in the posterior wall of the left ventricle, with dimensions of 21.17 mm, containing fibrin deposits.

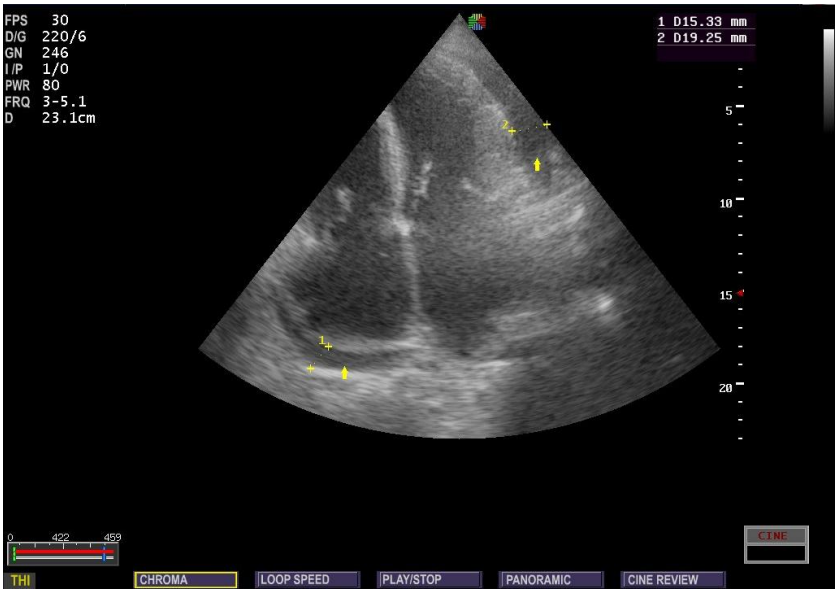

Fig. 3. Ultrasound 2D apical 4-room section, which highlights the pericardial fluid disposed in the anterolateral wall of the left ventricle of 19.25 mm and the free wall of the right atrium of 15,33 mm without ultrasound resemble tamponade.

A computed tomography (CT) scan of the chest revealed no evidence for acute lung injury, aortic dissection, or tumor lesions. Infectious, neoplastic, traumatic, uremic, post heart attack pericarditis or aortic dissection being excluded, thyroid dysfunction was taken into account and, in this regard, we dose serum thyroid-stimulating hormone (TSH) was 96.8 μUI / ml, free T3 2.9 ng/dl, free T4 0.3 pg/ml, anti-peroxidase (TPO) 372U/ml, and anti-thyroglobulin 834U/ml with a thyroid ultrasound without changes of position, size or structure. Once diagnosis settled, in the absence of signs of tamponade, pericardiocentesis was not performed (fig. 3).

Treatment was started with low doses of levothyroxine initially with 12.5μg and increased at 25μg after the first week and fitting according to thyroidian parameters. The patient was evaluated at 1, 3 and 6 months.

Restoring euthyroidism was correlated with clinical improvement and cardiovascular and neurological status, radiographic remission and regression to extinction of pericardial effusion on repeated echocardiogram.

DISCUSSION

Chronic autoimmune thyroiditis may eventually cause hypothyroidism, mainly via destruction of thyrocytes. The serological hallmark of Hashimoto's disease is the presence of high titers of thyroid peroxidase (TPO) auto antibodies. Elevated titers of anti-TPO simply show the presence of an autoimmune reaction against the thyroid and may be associated with hypothyroidism (most common) as well as with hyperthyroidism.

The diagnosis of hypothyroidism is difficult because hypothyroidism in adults and especially the elderly, classic, has an insidious onset with a range of nonspecific symptoms which may delay diagnosis for months or even years. Clinical features in hypothyroidism, such as weight gain, fatigue, intolerance of the cold, constipation, dry skin, oedema and muscle weakness, decreased osteo-tendinous reflexes (due to thyroid hormone action on the nervous system) are usually subtle and can be overlooked (7). The diagnosis is rarely made solely on clinical grounds, especially the elderly, who are often faced with either depression or dementia.

The occurrence of pericardial effusion in hypothyroidism appears to be related to the severity and duration of disease. The incidence of pericardial effusion is reported as 3% in the early mild stage reaching up to 80% of cases when myxedema is present (6).

In contrast to the frequent occurrence of pericardial effusion in patients with hypothyroidism, massive pericardial effusions are rarely associated with tamponade. Cardiac tamponade in patients diagnosed with hypothyroidism is probably as rare as it is due to pericardial distensability and the slow accumulation of fluid, allowing significant fluid accumulation without hemodynamic compromise (8). A variety of medical conditions, including malignant tumors, may lead to pericardial effusion. The presumptive mechanism underlying exudative pericardial effusions is extravasation of hygroscopic mucopolysaccharides into the pericardial space along with increased capillary permeability, decreased lymphatic drainage, and increased retention of salt and water (8). Due to its insidious onset, a pericardial effusion secondary to hypothyroidism frequently occurs without hemodynamic change, and is apparent only on echocardiography (9). Such findings in

an asymptomatic elderly patient can be misleading and may lead to unnecessarily invasive procedures such as pericardiocentesis (9). Using echocardiography it can be detected a pericardial effusion with a sensitivity of 96%, specificity of 98% and overall accuracy of 97.5% (10). Suggestive clinical signs of hypothyroidism and thyroid function evaluation in patients are crucial for an early diagnosis.

Therefore, hypothyroidism should be excluded in all patients with unexplained pericardial effusion etiology, not only in patients with clinically evident hypothyroidism or elder. Finally, once the diagnosis has been established, treatment with thyroid replacement hormones usually leads to the resolution of the effusion over 2–12 months without sequel.

CONCLUSIONS

This case report represents a typical primary hypothyroidism (autoimmune) and shows all the clinical aspects of these diseases. Basically we talked about a severe myxedema with the involvement of internal organs in an elderly woman and the euthyroidism restoration, under thyroid replacement therapy, was correlated with the clinical improvement, cardiovascular and neurological status, with radiographic remission and regression to extinction of pericardial effusion, at 6 months without sequelae.

EFFECT OF ORAL LOW DOSE CLONIDINE PREMEDICATION ON POSTOPERATIVE PAIN IN PATIENTS UNDERGOING ABDOMINAL HYSTERECTOMY: A RANDOMIZED PLACEBO CONTROLLED CLINICAL TRIAL (Abstract): This study evaluated the effect of oral low dose clonidine premedication on postoperative pain and hemodynamic status of the patients during abdominal hysterectomy under general anesthesia. **Methods:** This study is a randomized, placebo controlled double-blinded clinical trial. After approval of the study protocol by the Ethics Committee 60 patients were recruited and written informed consents were obtained. Two hours before surgery, patients in the treatment group (n=30) received a single oral dose of 100 microgram of clonidine and those in the placebo group received an oral dose of placebo (n=30). The severity of postoperative pain was assessed at 2nd, 6th, 12th and 24th hours after the operation using the visual analog scoring system (VAS score). Also the total dose of administered analgesics during 24 hours after the surgery and the interval between the surgery and the first request of analgesic were compared between the two groups. Systolic blood pressure and pulse rate were recorded during the surgery and at the post anesthesia care unit. Drug related adverse effects were also evaluated. **Results:** Postoperative pain VAS during 24 hours after the surgery was significantly (P=0.001) lower in clonidine group (3.86±0.89) compared to the placebo group (4.86±0.93). Also, the interval between surgery and the first request of analgesic in clonidine group was4.13±3.27 hours on of longer duration (P=0.02) compared to 2.88±3.74 hours in placebo group. The mean heart rate and systolic blood pressure were lower in the clonidine group. **Conclusion: A single** oral 100 µg dose of clonidine administered 2 hours before abdominal hysterectomy significantly reduces the severity of postoperative pain. **Keywords:** POSTOPERATIVE PAIN, CLONIDINE, HYSTERECTOMY

Prevention and treatment of postoperative pain and associated complications like nausea and vomiting are critical issues in postoperative care. Unless managed adequately, acute postoperative pain can adversely affect the outcome of surgery and may lead to a condition of chronic pain. Opiates such as morphine are the standard drugs used to alleviate postsurgical pain. However, although opiates produce antinociception through their µ receptor agonist activity, they also activate the N-methyl-d-

aspartate (NMDA) receptor, resulting in hyperalgesia and the development of tolerance to opiates. In addition, opiates have several side effects which can result in significant complications including hyperalgesia. For these reasons we prefer to use adjuvant drugs that alleviate pain and reduce postoperative consumption of the opioids.

Postoperative pain management is accomplished by different methods including the systemic (oral, intramuscular, or intravenous), regional (epidural or intrathecal), or transdermal administration of analgesic agents, and less commonly cutaneous electrical stimulation (1, 2).

Although the mechanisms responsible for the genesis of acute pain are not completely understood, it is believed that sensitization of the neurons in the dorsal horns of the spinal cord contributes significantly to postoperative pain. Acute pain is known to trigger a cascade of messages from the spinal cord and the release of aminoacids and neuropeptides from afferent fibers. The resulting stimulation of the NMDA receptor causes hyper stimulation of the spinal dorsal horn neurons and prolongation of postoperative pain (3, 4). In patients with history of ischemic diseases, postoperative pain increases the sympathetic tone and enhances the risk of myocardial ischemia and myocardial infarction (5). Consequently, morbidity and mortality are increased. Hysterectomy is one of the most prevalent surgeries in women and is the definite treatment for abnormal uterine bleeding (AUB) because it yields the most satisfactory results compared to alternative therapies. Abdominal hysterectomy with or without salpingo-ophorectomy is associated with moderate to severe pain (6).

Clonidine is an alpha-2-adrenergic receptor agonist (7) used chiefly as an antihypertensive agent. Through stimulation of the α-2 receptor and the negative feedback at the presynaptic neurons, significant reductions in the sympathetic activity occur at the level of the heart, the kidneys, and the peripheral blood vessels lowering cardiac output, vascular resistance, and blood pressure. Clonidine is also effective in the prevention of vascular headaches by blocking vasomotor reflexes. In addition, clonidine is used in the treatment of dysmenorrhea and the control of opioid withdrawal symptoms. It is also used as an adjuvant in the management of attention deficit hyperactivity disorder (ADHD). Its half-life is 12-16 hours and its side effects include drowsiness, sedation, headache, vertigo, nausea and vomiting.

The aim of the present study is to corroborate and expand the observations reported in previous studies (8, 9; 10, 11, 12) which evaluated the use of clonidine as a premedication in the management of postsurgical pain.

MATERIAL AND METHODS

After approval by our institutional Ethics Committee, the study was registered in Iranian registry of clinical trials (http://irct.ir) as IRCT201108202963N3. Sixty women with ASA physical status I or II who were candidates for abdominal hysterectomy under general anesthesia were recruited in this randomized, double blinded placebo controlled clinical trial. Randomization was done by an epidemiologist using a computer generated table of random numbers. Patients were randomly allocated to either to the placebo group or the clonidine group (30 patients each). Sample size estimation was based on α=0.05 and ß error=0.8 and based on previ-

ous studies S=2. Assuming possible 10% loss to follow-up, 30 patients were needed for each group. The patients with chronic pain, opium addiction, or allergy to clonidine were excluded from the study. At the beginning of the study, patients in the two groups were similar in terms of age, body weight, systolic blood pressure and heart rate (tab. I). Two hours before surgery patients received a single oral dose of either placebo or 100 µg of clonidine. The drug administration occurred under supervision of an anesthesiologist who was not aware of patients' group assignment. Induction and maintenance of anesthesia was with 2 mg/kg propofol and also 2 mg/kg atracurium and then infusion of propofol 150 microgram/kg/h and O2 – N2O 50% - 50% for all patients. 5 mg morphine was given to all patients after induction of anaesthesia. After administration of 0.5 mg /kg atracurium IV, patients were intubated. All surgeries were done by same surgeon using the same surgery method. The intensity of postoperative pain was evaluated by researcher using patient` self report and quantified using a 10 cm visual analog scale (VAS) where zero indicates no pain at all and a score of 10 indicates very severe, intolerable pain. VAS was recorded at 2nd, 6th, 12th and 24th hour after the operation. Morphine was the only analgesic drug used in the first 24 hours after surgery. If the VAS score was more than 4, a 5 mg morphine dose was administered intramuscularly to maximum dose of 5 mg/6 hours. The two groups were compared with respect to the total dose morphine administered during the first 24 hours after the surgery and the time interval between the end of surgery and the first request of analgesia. Systolic blood pressure and heart rate were recorded before induction of anesthesia, immediately, 5 minutes, and 30 minutes after laryngoscopy and intubation and also at the end of the surgery and in the post anesthesia care unit (PACU). Patients were also monitored for drug related side effects. All measurements and data records were done by a resident of anesthesiology who was not aware of patients` group assignment. Statistical analyses were performed using SPSS 15.5 software and differences were evaluated using Students` T-test, Mann Whitney and Fishers exact tests. P-values <0.05 indicate statistically significant differences.

TABLE I

Patients' ages, body weights, and hemodynamics at the beginning of the study

	Clonidine	**Placebo**	**P-value**
Age	45.86 ± 4.06	48.16 ± 4.48	NS
Body Weight	64.56 ± 13.29	68.80 ± 12.88	NS
Systolic BP	116 ± 11	120 ± 20	NS
Heart Rate	91 ± 16	93 ± 17	NS

NS = not significant

RESULTS

A total of 71 patients were evaluated for the study, 11 patients were excluded before randomization because they did not meet the inclusion criteria and 60 patients were recruited and randomly assigned to the placebo or the clonidine group (30 patients per group).

VAS scores at the 2nd and 6th hours after the operation were not significantly different between the groups (P>0.05), but at the 12th and the 24th hours after the operation the VAS scores were significantly lower in the clonidine group (tab. II).

Compared to placebo group, the patients in the clonidine group had lower mean heart rate and mean systolic blood pressure before induction of anesthesia, immediately after laryngoscopy and 5 minutes after tracheal intubation (P<0.05). Also mean systolic blood pressures at the 30th minute after tracheal intubation was lower in the clonidine group (P<0.05) (tab. III). Although VAS scores at 12th and 24th hours after the operation were 10% and 20% lower in the patients who received clonidine, the consumption of opioid in the first 24 hours after the operation was not different (fig. 2). The time interval between the end of operation and 1st request for analgesia was 40% longer in the clonidine group (4.13±3.27 hours in clonidine group vs. 2.88±3.74 hours in placebo group, Mann-Whitney Test, P=0.02). No difference was detected between the two groups in terms of the common side effects related to clonidine, and none of the patients had pruritus or bleeding at the field of surgery.

TABLE II

Mean ±SD of VAS pain scores at different times after surgery.

Measurement Time / Group	2nd hour after surgery	6th hour after surgery	12th hour after surgery	24th hour after surgery
Clonidine	6.76±1.33	6.20±0.71	5.83±0.91	3.86±0.89
Placebo	7.43±1.5	6.6±1.1	6.46±1.16	4.86±0.93

DISCUSSION

Prevention and treatment of postsurgical pain is of critical importance in postoperative care.

Perioperative pain is thought to involve multiple mechanisms, including sensitization of peripheral somatic and visceral nociceptive nerve terminals as well as cen-

tral neurons, nociceptive transduction, , and loss of local and descending inhibition of neurons in the brainstem and spinal cord (13).

There is ample evidence that perioperative systemic administration of α2-agonists decreases postoperative opioid consumption, pain intensity, and nausea (14). Alpha2-agonists inhibit the release of P-substance in dorsal root neurons (15). Also stimulation of α_2-adrenoceptors in neural terminals may decrease pain by preventing norepinephrine release (16).

The results of the present study demonstrate that a single oral dose of clonidine (100 μg) administered two hours before surgery can lower postoperative pain scores at 12th and 24th hours after the operation in the women who underwent abdominal hysterectomy. Time interval between the end of surgery and need for first dose of analgesic was significantly longer without notable side effects. Heart rate and systolic blood pressure after laryngoscopy and intubation were lower in the patients who received clonidine compared to those who received placebo. Surprisingly the patients in the clonidine group had lower incidence of nausea than those in the placebo group.

Hidalgo MP et al in 2005 showed that three doses of 100 μg clonidine (at the night before surgery and first hour and 24 hours after surgery) can decrease post hysterectomy pain (8). In this study the patients received a total of three 100- g doses of clonidine compared to a single dose in our study. Hidalgo and co-workers did not discuss possible complications that might be associated the higher dose of clonidine.

In a study in 2006 administration of 2-4 mg/kg oral clonidine as premedication in children can decrease postoperative pain and anxiety (9). These results were confirmed by Toru Goyagi et al. In this study after adding oral clonidine to epidural morphine, postoperative pain was decreased without any complications (10). In a study in 2007 Persec J concluded that administration of clonidine before surgery will decrease postoperative pain more than administration of clonidine after surgery or placebo (17). Our study supports this conclusion. However, in our study there was no significant difference between groups with respect to the total consumption of morphine. This difference may be due to lack of cooperation by the nursing staff on the ward who may inject the analgesic without considering VAS score.

Clonidine can decrease stress response and improve the patient's hemodynamic status by decreasing the level of circulating catecholamine. Our study shows that clonidine decreases systolic blood pressure (SBP) and Heart rate (HR) during surgery and recovery.

Shivering Singh et al in 2011 concluded that in patients who were candidates for laparoscopic cholecystectomy, 150 μg oral clonidine as premedication administered 90 minutes before the induction of anesthesia can improve the patient's hemodynamics and prolong the time between surgery and the first request for analgesia (11). Nausea is one of the most prevalent complications after surgery. In our study nausea and vomiting occurred at a significantly lower rate in the clonidine group, but the two groups were similar with respect to other adverse effects. In this respect our results were similar to the findings reported by Farmery et al (12).

In our study the administration of morphine was based on the patient's request,

and there was no significant difference in morphine consumption between the two groups at any point during the first 24 hours after surgery.

The long lasting effect of clonidine despite its 12 hours half-life may be due to its diverse actions modifying not only the adrenergic component to pain perception but also the neurohumoral response to tissue injury (18). A study in China on rats showed that the effects of clonidine were blocked by the α2-adrenoceptor antagonist yohimbine and partially reversed by the μ-opioid receptor antagonist naloxone (19).

CONCLUSION

A single oral dose of 100 μg of clonidine as a premedication in patients undergoing abdominal hysterectomy improves perioperative hemodynamic stability and reduces postoperative pain intensity without any considerable side effects. Clonidine is likely to play an increasing role in clinical practice in perioperative pain management.

NEWS

IS INTRAOPERATIVE HISTOLOGY IMPORTANT IN PREDICTING INFECTION IN PATIENTS UNDERGOING REVISION ELBOW ARTHROPLASTY?

A recent study by Ahmadi and co. brings new informations regarding the role of intraoperative histology in the diagnosis of infection in patients undergoing revision elbow arthroplasty. In the study were included 296 consecutive revision elbow procedures, from witch 227 intraoperative histology and operative samples for culture were obtained. The number of procedures with histology read as consistent (acute inflammation) was 33 (14.5%). Intraoperative cultures were positive in 39 procedures (17.2%). Intraoperative histology was considered true positive (both histology and cultures positive) in twenty arthroplasties (8.8%), true negative (both histology and cultures were negative) in 175 arthroplasties (77.1%), false positive (the histology was positive but the culture was negative) in thirteen arthroplasties (5.7%), and false negative (the histology was negative but the culture was positive) in nineteen arthroplasties (8.4%). With regard to intraoperative histology, the sensitivity was 51.3%, the specificity was 93.1%, and the accuracy was 85.9%. The positive predictive value was 60.6% and the negative predictive value was 90.2%. The study concluded that intraoperative histology had a high specificity and negative predictive value, but a low sensitivity and positive predictive value for predicting infection in the setting of revision elbow arthroplasty and it should be used in conjunction with other studies to definitively establish the diagnosis of infection in the setting of revision elbow arthroplasty. (Ahmadi S, Lawrence TM, Morrey BF, Sanchez-Sotelo J. The value of intraoperative histology in predicting infection in patients undergoing revision elbow arthroplasty. *J Bone Joint Surg Am.* 2013; 95:1976-1979).

EBSTEIN'S ANOMALY (Abstract): Ebstein's anomaly is a rare congenital heart disease, accounting for less than 1% of all congenital heart diseases, characterized by a wide clinical, electrocardiographic, echocardiographic, anatomic and prognostic polymorphism. The disease can be fatal since birth or may remain asymptomatic until adulthood, sometimes being associated with septal defects, transposition of great vessels, preexcitation syndromes, or left ventricular noncompaction. The genetic changes underlying this syndrome are not fully known, but in the cases associating left ventricular nonompaction a mutation in MYH7 gene encoding the β-myosin heavy chain was recently detected. The authors present 2 cases of Ebstein's anomaly with different onset and course and discuss the current clinical, electrocardiographic and echocardiographic criteria used for prognostic stratification of Ebstein disease in relation to international literature. **Keywords**: EBSTEIN'S ANOMALY, TRICUSPID VALVE, ELECTROCARDIGRAPHY, ECHOCARDIOGRAPHY.

Ebstein's anomaly is a rare congenital cardiac malformation characterized by a combination of pathological anatomical and functional changes of the tricuspid valve, right ventricle and atrium. The diagnosed cases account for less than 1% of all congenital cardiac malformations, the prevalence being approximately 1 in 20,000 live births (1-4). The malformative complex affecting the tricuspid valve and right ventricle is characerized by many variations and degrees of severity, conferring a significant clinical electrocardiographic, echocardiographic and evolutive polymorphism to the disease. The main lesion is represented by the apical displacement of the septal and posterior tricuspid valve leaflets by over 8 mm/m^2 body surface area. Functionally, the malformation causes atrialization of part of the right ventricle, and different degrees of tricuspid regurgitation, sometimes associated with stenosis. The disease can be associated with other cardiac malformations, most commonly with interatrial septal defect or patent foramen ovale (80-94% of patients) and rhythm and conduction disorders, due to the discontinuity of intracardiac excito-conductor system (3-6). The authors discuss the peculiarities encountered in two cases of Ebstein's anomaly diagnosed in adults and compare them with the literature data.

CASES PRESENTATION

Case 1. A 51-year-old man was admitted for cardiovascular symptoms that occurred about 2 years earlier and gradually worsened, including NYHA class II exertional dyspnea, atypical chest pain without specific radiation, enhanced by mental strain and fatigue. History did not reveal other cases of congenital heart disease in consanguineous relatives, potentially teratogenic drug use, or pregnancy-related disease of his mother. The patient was nonsmoker, and physical examination showed longilin, hypoasthenic constitutional type, poor nutritional status (body mass index – BMI, 17 kg/m^2), jugular pulse synchronous with carotid pulse, apex shock in the V-th left intercostal space 1 cm outside the midclavicular line, normal blood pressure, at auscultation heart sounds I and II were duplicated, there was a mesosystolic click followed by a short systolic murmur, telesystolic, at the apex, with highest intensity in the V-th left intercostal space, parasternally, and at the xiphoid appendix, accentuated by post-inspiratory apnea. The antero posterior chest radiograph revealed a slight bulging of the right lower and left middle arches with a cardiothoracic index (CTI) at limit, of about 0.44. Electrocardiography showed a sinus rhythm (SR) with heart rate of 60 beats/min, QRS axis at +30°, PQ interval = 0.14 s, and prolonged QRS duration (0.14 s in standard leads and 0.18 s in precordial leads) suggestive of right bundle branch block (RBBB) (fig. 1).

Cardiovascular assessment continued with the study of standard sections used for transthoracic echocardiography, 2D mode, color Doppler, continuous and pulsed: parasternal long axis - normal-sized left heart (left ventricle – LV, 39/26 mm, interventricular septum – IVS, 9 mm, left ventricular posterior wall – LVPW, 9.5 mm), while the right heart has dilated cavities (right atrium – RA, 69/39 mm, right ventricle – RV, 79/49 mm), paradoxical IVS movement, the position of the tricuspid valve is diverted to the anterior part and is visible concomitantly with the mitral valve and its excursions are large and closure delayed; anterior mitral valve presents a 6mm telesystolic prolapse and minor mitral regurgitation; apical four-chamber view: septal insertion of tricuspid valve at 26.8 mm inferoapical to the mitral valve, Doppler grade III tricuspid regurgitation (fig. 2); the calculated atrialized RV portion represented approximately 25% of total RV area.

Contrast echocardiography excluded the presence of interatrial communication. Infectious endocarditis prophylaxis, limited physical activity, and low dose diuretics were recommended.

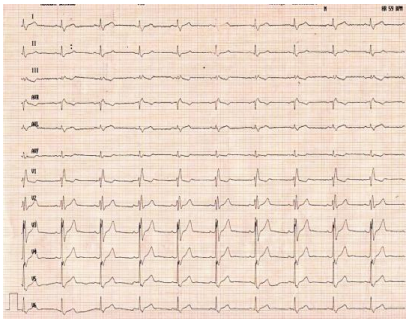

Fig. 1. Case 1 electrocardiogram. SR 60/min, PQ=0,14 s, RBBB

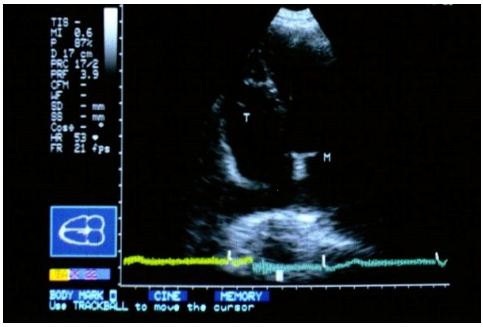

Fig. 2. Case 1 ecocardiography Apical four-chamber view

Case 2. A 34-year-old female patient presenting since childhood repeated fainting spells, intermittent headache, and decreased execise tolerance was diagnosed at age 14 with Ebstein's anomaly, severe form. The patient was recommended antiplatelet therapy and limited physical exertion; her condition had improved and, later on she carried two pregnancies to term, delivery by cesarean section. This year, the patient's condition worsened again, with rest and exertional dyspnea, chest pain, cyanosis, dizziness, headache and more episodes of loss of consciousness. Emergency craniocerebral computed tomography revealed a moderate diffuse cerebral atrophy. Cardiovascular assessment showed: grade I obesity (BMI 31.5 kg/m^2), increased cross-sectional cardiac dullness, sound I diminished, sound II duplicated, systolic murmur grade IV/VI in the III-rd and IV-th left intercostal space; electrocardiogram: 60/min SR, QRS axis at + 30°, first-degree atrioventricular block (AVB) (PQ = 244 ms), major right bundle branch block, RA and RV overload (fig. 3); echocardiography: low insertion of the tricuspid valve (at 47 mm from the insertion of mitral valv, cusp inserted into the free wall of the right ventricle, separately from tricuspid ring) causing atrialization of a large RV portion (38% of RV area) (fig. 4); left cavities were compressed by the right ones, paradoxical IVS motion; Doppler grade III tricuspid insufficiency and Doppler grade I aortic insufficiency; in the interatrial septum (IAS) foramen ovale was open and had a small bidirectional shunt at color Doppler.

Given the worsening of cardiac dyspnea, presence of syncopes, cyanosis and echocardiographic appearance, the patient met the indication for tricuspid valve prosthetic replacement or valvular reconstruction, but until then the continuation of antithrombotic and diuretic therapy was recommended.

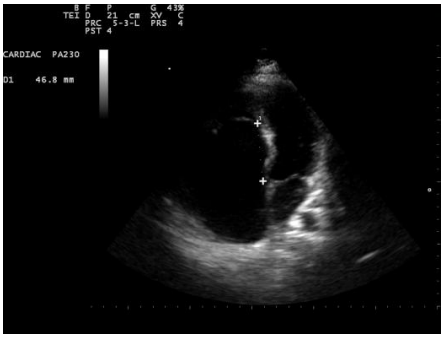

Fig. 4. Ecocardiography case 2 – apical 4 chamber view, dilatation of right chambers

DISCUSSION

In Ebstein's anomaly, tricuspid valvular disease is highly variable and causes a wide anatomic, clinical and laboratory spectrum, although the malformation is quite uncommon. The presented cases illustrate this variability. The first patient is a man in which the disease has progressed discretely and passed almost unnoticed until the age of 51 years, the second case is a relatively

young female who, despite two childbirths, has been symptomatic since childhood and last year symptoms worsened so much that surgery was indicated. This prognostic difference in is related to the echocardiographic changes: the apical displacement of the tricuspid valve was more significant in the second case and determined an over 30 percent RV atrialization, considered a sign of severity.

For practical reasons, the studies and anatomical models have gradually been correlated with the echocardiographic findings and classifications of the disease occurred. The best known were the 1988 Carpentier's anatomo-functional classification (7) and the echocardiographic classification developed by Celermajer in 1994 (8), its goal being to determine, based on the calculation of echocardiographic score, the severity of this condition since birth. According to Carpentier classification, the anomaly may fall into one of four types:

- Type A – the atrialized RV portion is small, anterior leaflet of tricuspid valve is mobile and the septal one is minimally displaced;

- Type B - RV retains functionality, anterior leaflet of tricuspid valve is still mobile, without tethering, but the septal and posterior leaflets are displaced apically more than 25 mm;

- Type C – agenesis of the tricuspid valve posterior leaflet, hypoplasia and severe displacement of the of tricuspid valve septal leaflet, and tricuspid valve anterior leflet partially attached to RV wall, can cause obstruction of the right ventricular outflow tract;

- Type D – the right ventricle is almost completely atrialized, tricuspid valve anterior leaflet is attached to the ventricular wall, forming a second endocardium (5, 7).

Celermajer proposed calculating an echocardiographic ratio of the area of right atrium and the atrialized RV portion compared with that functional RV and left heart, resulting the following classification: grade 1 ratio < 0.5; grade 2 - ratio of 0.5 to 0.99, grade 3 - ratio 1 to 1.49, grade 4 - ratio above 1.5 (4, 8). With reference to these classifications, both presented cases fit Carpentier' type B, but the calculation of echocardiographic ratio made possible the first patient to be classified as Celermajer grade 2, and the second Celermajer grade 3, indicating a more severe prognosis. The second case also presented a patent foramen ovale. In more than half of the patients with Ebstein's anomaly an interatrial communication of secundum atrial septal defect type or patent foramen ovale is associated (4).

Although electrocardiography is a classical method that did not seem first line for stratifying the severity of Ebstein's anomaly, some very recent research support a close relationship between the malformative complex morphology assessed by echocardiography or nuclear magnetic resonance and more elecrocardiographic parameters. Assenza GE et al. evaluated several parameters that can be measured on surface ECG: P wave amplitude in DII, PR interval, QRS duration and morphology and correlated them with morphological and magnetic resonance data. For the first time they propose the systematic measurement of S-wave upstroke and revealing a particular pathological aspect present in the terminal portion of the QRS complex or initial ST segment as a small negative wave, below 0.5 mV, aspect called "QRS fractionation". Increased QRS duration

especially in its terminal portion and its fractionation are parameters that correlate well with disease severity, decreased exercise capacity, systolic dysfunction, and RVatrialization (3). In our study, the first patient presented an early repolarization syndrome (known to accompany Ebstein's anomaly in a variable percentage, between 0 and 44%) (11) and QRS prolongation with RBBB aspect, while the second patient presented AVB grade I and QRS fractionation, elements of severity and poor prognosis (3, 4). For patients with Ebstein disease and asymptomatic preexcitation syndrome, Pappone et al. have proposed the assessment of arrhythmic risk by electrophysiological studies and ablation procedures for high-risk patients (9, 10).

The presented cases had isolated Ebstein's anomaly, but in the literature numerous complex cases associating other cardiac malformations (pulmonary valve stenosis or atresia, and ventricular septal defects, transposition of great arteries, noncompacted LV) are reported. More cases of Ebstein's anomaly associated with LV noncompaction are the result of mutations in sarcomere encoding genes, especially MYH7 gene encoding β-myosin heavy chain (11).

Given the discussed severity criteria, the indication for surgery is limited only to the second case. The literature reported medium and long-term favorable results following both prosthetic intervention and plasty consisting in creating a unicusp valve from the anterior leaflet, plicature of the free wall of atrialized portion and posterior tricuspid annuloplasty (12-14).

CONCLUSIONS

Ebstein's anomaly is one of the rare congenital heart malformations with a highly variable evolutionary spectrum, ranging from fatal cases since childhood to adult asymptomatic cases discovered fortuitously. Patients should be assessed periodically by cardiologists experienced in the diagnosis of congenital heart diseases using electrocardiography, echocardiography, electrophysiology studies and magnetic resonance imaging.

FACTORS RESPONSIBLE FOR RELATIVE POSITION OF INTERPROXIMAL

PAPILLA IN HEALTHY SUBJECTS

A group of Korean researchers conducted a study that examined the factors that can be associated with the appearance of the interproximal papilla.Were examined one hundred and forty-seven healthy interproximal papillae between the maxillary central incisors (male, 74; female, 73; average age, 25.36±7.58 years). A digital photograph and periapical radiograph of the interdental embrasure were taken for each subject using a 1-mm grid metal piece. The recorded parameters were: the amount of recession of the interproximal papilla, contact point-bone crest distance, contact point-cemento-enamel junction distance, cemento-enamel junction-bone crest distance, inter-radicular distance, tooth shape, embrasure space size, interproximal contact area, gingival biotype, papilla height, and papilla tip form. The amount of recession of the interproximal papilla was associated with: 1) increase in contact point-bone crest, contact point- cemento-enamel junction, and cemento-enamel junction -bone crest distance; 2) increase in the inter-radicular distance; 3) triangular tooth shape; 4) decrease in the interproximal contact area length; 5) increase in the embrasure space size; 6) flat papilla tip form. The amount of gingival recession was not associated with the gingival biotype or papilla height. In the triangular tooth shape, the contact point-bone crest distance and inter-radicular distance were longer, the interproximal contact area length was shorter, and the embrasure space size was larger. The papilla tip form became flatter with increasing inter-radicular distance and cemento-enamel junction-bone crest distance. The relative position of the interproximal papilla in healthy subjects was associated with the multiple factors and each factor was related to the others. A triangular tooth shape carries a higher risk of recession of the interproximal papilla because the proximal contact point is positioned more incisally and the bone crest is positioned more apically. This results in an increase in recession of the interproximal papilla and flat papilla tip form. (Kim JH, Cho YJ, Lee JY, Kim SJ, Choi JI. An analysis on the factors responsible for relative position of interproximal papilla in healthy subjects. *J Periodontal Implant Sci*, 2013; 43 (4): 160-167)

CLINICAL AND THERAPEUTIC ASPECTS OF AMIODARONE INDUCED THYROID DYSFUNCTION

Irina Iuliana Costache[1], Ana Clara Aprotosoaie[2]
University of Medicine and Pharmacy „Grigore T. Popa" – Iasi

CLINICAL AND THERAPEUTIC ASPECTS OF AMIODARONE-INDUCED THYROID DYSFUNCTION (Abstract): Discovered in 1961 by Tondeur and Binon, two Belgian chemists, amiodarone was widely used, especially in Europe, initially as an antianginal agent, and later as an antiarrhythmic one (following the experiments conducted at the University of Oxford by Dr. Bramah Singh). Thus, the role of amiodarone was reconsidered, becoming, together with Sotalol, a class III antiarrhythmic – a group characterized by the action of extending the potassium channels refractory period. In time, amiodarone has proven its effectiveness in the treatment of both atrial and potentially malignant ventricular arrhythmias, being considered one of the antiarrhythmic agents involved in the prevention of sudden cardiac death due to arrhythmias. In December 1985, amiodarone was approved by the FDA (Food and Drug Administration) for the treatment of atrial fibrillation and the prevention of recurrent ventricular tachycardias. Despite this positive effect, the prescription of amiodarone began to be limited because serious side effects occurred, some of them disastrous, which were associated with the chronic use of the substance. **Keywords:** AMIODARONE, ANTIARRHYTHMICS, THYROID DYSFUNCTION.

Amiodarone is a class III antiarrhythmic (according to the classification of Vaughan and Williams) whose effectiveness in the treatment and the prophylaxis of atrial and ventricular rhythm disorder (especially of those with life-threatening risk) is unanimously accepted (1). Over time, its beneficial effects, however, have been far outweighed by the severe side effects occurred on various organs, the most important of them being the fact that it affects the thyroid, the liver, the lungs, the eyes, the kidneys, the skin, and the nervous system.

As chemical structure, the amiodarone molecule contains a benzofuran cycle and a phenyl ring with two iodine atoms and two aliphatic radicals (fig.1).

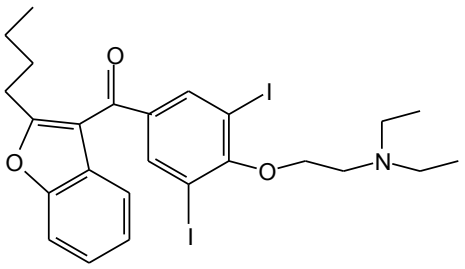

Fig. 1. Amiodarone

Its action is that of blocking at the same time the sodium, potassium and calcium channels. It presents obvious structural similarities with thyroxine, a hormone produced and released by the thyroid gland (2).

Pharmacokinetics

Amiodarone is a lipophilic substance, with a high volume of distribution, long and unpredictable half-life (estimated at 100 days), with the possibility of accumulation in the lungs, liver, skin, fat tissue, nervous system and the thyroid. Accumulation in the kidneys is slightly lower compared to other organs. The release from these tissues is much slower (it may last up to 9 months). These effects are due to its major metabolite that is created in the liver by dealkylation (CYP 3A4-mediated) – up to the final product - desethylamiodarone (DEA), which remains pharmacologically active for a long period of time (half-time: 57±27 days) (2).

Between 66-75% of the quantity of amiodarone that is administered is eliminated from the body via the bile and the stool, instead the DEA intra-thyroidian concentration remains high (2).

THYROID DAMAGE

Thyroid abnormalities were observed at a rate between 14-18% of the patients receiving the minimum dose of amiodarone. The effects at the thyroid level are variable:

- abnormal thyroid function detected only by periodic laboratory tests (TSH, FT4, FT3) in the absence of any clinical picture;

- clinically manifested thyroid dysfunction: under the form of amiodarone-induced thyrotoxicosis, or hypothyroidism. Both can occur on a previously normal thyroid gland and in the context of a pre-existing thyroid damage that they can worsen (3, 4, 5).

Regarding thyroid damage, the mechanisms of action of amiodarone are particularly complex: amiodarone inhibits the action of an enzyme – deiodinase - and thereby decreases peripheral conversion of thyroid hormones. It also decreases their renal elimination, it increases T4 and it decreases T3 by about 25% and it inhibits the entry of T4 and T3 in peripheral tissues. The level of T4 increases by 40% within 1-4 months of treatment with amiodarone. The inhibition of deiodinase activity in the pituitary gland can be noticed after the first 3 months of treatment and it leads to the increase of the level of thyroid stimulating hormones. Amiodarone together with its metabolite has a direct cytotoxic effect on the thyroid follicular cells, the result being a destructive thyroiditis. It acts as a competitive antagonist of T3 at the heart level.

Amiodarone-induced thyroid damage can take the clinical and biochemical picture either of hypothyroidism or hyperthyroidism.

An emergency might be, in some cases, only amiodarone-induced hyperthyroidism which in its turn can be of two types:

Type 1 - due to iodine excess in amiodarone which causes excessive synthesis of thyroid hormones; it usually occurs in subjects with prior thyroid damage (subclinical or clinically manifested);

Type 2 – it appears as an inflammatory process followed by destruction in patients with previously normal thyroid. A destructive thyroiditis appears with the release of hormones preformed from damaged thyroid follicular cells. This manner of evolution requires an emergency specific therapeutic conduct that involves glucocorticoids.

Combined forms of thyroid damage may rarely appear. From a biochemical

point of view, amiodarone-induced hyperthyroidism is characterized by very low levels of TSH, greatly increased FT4, and decreased FT3 during initial stages.

Causes and risk factors

The risk of developing thyroid damage under amiodarone treatment is independent of the daily or cumulative dose of amiodarone. There are studies that have shown that autoimmune thyroid damage is the main risk factor for developing hypothyroidism. At the same time, obesity and family history regarding thyroid disease could be considered predisposing factors. The presence of anti-thyroglobulin or thyroid antiperoxidase gives an estimated risk of 13% for developing hypothyroidism in women.

CLINICAL ASPECTS

The clinical picture is variable – from the absence of any symptom (it is the case of subclinical forms of disease), up to forms with dramatic and life threatening clinical manifestations. As "alarm" clinical elements for thyroid dysfunction which appeared under treatment with amiodarone can be included: signs and symptoms of cardiac decompensation, tachyarrhythmias, worsening angina phenomena, weight loss, and unexplained fatigue. Thyrotoxicosis can occur both during treatment with amiodarone, but also after several months of its discontinuation.

Amiodarone-induced thyrotoxicosis may result in the following symptoms:

- weight loss, heat intolerance, sweating;
- muscle weakness, permanent fatigue;
- emotional lability, hyperkinetic status (palpitations, newly emerging arrhythmias or the worsening of pre-existing ones);
- frequent stools, diarrhea;
- nervousness, anxiety, oligomenorrhea (4, 5, 6).

Amiodarone-induced hypothyroidism can result in:

- fatigue, lethargy, severe drowsiness, cold intolerance;
- weakness, constipation, slowness (in severe cases it can lead to mixedematous coma);
- menorrhagia in women;
- dry, rough skin;
- pericardial effusion (4, 5, 6).

It is worth mentioning that these symptoms are not specific to thyroid damage caused by amiodarone.

The thyrotoxic crisis is an acute and extremely serious complication which may occur in the evolution of the hyperthyroid patient (rare but possible in the context of amiodarone-induced thyrotoxicosis), which consists of massive, brutal body intoxication with thyroid hormones, associated with acute suprarenal insufficiency explained by excessive degradation of cortisol (4,5,7). Clinically manifested by agitation, delirium, fever, tachycardia, vomiting, diarrhea, severe arrhythmia (or the aggravation of the pre-existing ones), hypertension initially, then collapse and coma. Listed as therapeutic alternatives might be: synthetic antithyroid drugs, intravenous beta-blockers, corticotherapy (4, 5, 7, 8, 9).

Manifest or subclinical hyperthyroidism, particularly the forms with undetectable levels of TSH serum is correlated with a substantial increase in cardiovascular mortality (up to 20%). Factors associated with the increase of mortality in these situations are: arrhythmias (AF), embolic strokes (systemic), the aggravation of cardiac insufficiency, hypertension, pre-existing coronary disease (3,7). After

treatment with synthetic antithyroid drugs, certain symptoms, arrhythmias and the negative hemodynamic balance can sometimes persist despite the normalization of thyroid hormones. Studies have also shown that treatment with radioactive iodine may increase cardiovascular mortality. In patients with hyperthyroidism, a status of hypercoagulability and hipofibrinolisis which would increase the risk of thromboembolic events (especially the brain) (3, 4, 7, 8).

Laboratory diagnosis

Amiodarone-induced thyroid damage must be confirmed through laboratory tests that basically consist of specific hormonal determinations. They may be modified even in the absence of a clearly contoured clinical picture (subclinical affecting) (1, 5, 8).

For amiodarone-induced hypothyroidism, laboratory tests are similar to those of spontaneous hypothyroidism and they include: low levels of free T4 and elevated levels of serum TSH. Serum thyroglobulin is also elevated (due to stimulation by TSH) (4, 5, 6, 10).

In the case of amiodarone-induced thyrotoxicosis, laboratory tests objectify: undetectable levels of serum TSH and highly elevated levels of free T4 and T3 (4, 5, 6, 10).

Imagistic studies are necessary for recognizing the right type of thyrotoxicosis, on which the choice of treatment modality relies.

Thyroid ultrasound - may indicate in Type 1 ahypoechoic or nodular aspect with thyroid size increase (6).

Radioactive iodine uptake studies, normal or elevated, also direct to type 1 (6).

If thyroid biopsy is performed, histological changes specific for amiodarone therapy are: diffuse follicular fibrosis, epithelial atrophy, apoptosis, necrosis, vacuolated cells arranged in the form of intraluminal aggregates, lymphocytic infiltrates (6, 9).

THERAPEUTIC ASPECTS

Therapeutic conduct for patients with amiodarone-induced thyroid dysfunction, regardless of type and form, remains a challenge because there is insufficient data on the optimal treatment (6). For patients who associate cardiac damage, collaboration between cardiologist and endocrinologist is essential.

In the case of thyrotoxicosis, making the difference between the two types is mandatory for the choice of therapy.

The decision to interrupt or not the treatment with amiodarone usually belongs to the endocrinologist, but he will take into account the severity of concomitant cardiac damage, which could highly obscure the prognosis. The evolutionary ways after stopping amiodarone can be extremely polymorphic. Thus, usually, after stopping amiodarone, mild forms of thyrotoxicosis regress spontaneously in approximately 15 - 20% of the cases (6). Some of the patients with type 2 become euthyroidia affected within 3-5 months after stopping the treatment, while in other cases thyrotoxicosis may last up to 8 months even after stopping the drug administration (6, 9). There are also situations in which stopping amiodarone may worsen the symptoms, and in severe forms of thyrotoxicosis it may lead to the emergency thyroidectomy (6).

In type 1 – therapeutic conduct involves, besides stopping amiodarone, the administration of synthetic antithyroid drugs (higher doses than the usual ones) to block the synthesis of thyroid hormones. In type 2, long-term corticosteroid therapy is

indicated (to inhibit the activity of deiodinase), and even thyroidectomy in the cases that do not respond to the above mentioned treatment (4, 6 10).

As alternative treatments, in the case of thyrotoxic crises there are mentioned: synthetic antithyroid drugs, intravenous beta-blockers, corticotherapy.

Hypothyroidism usually remits after the elimination of amiodarone. In some cases amiodarone associated with thyroid hormones can be continued (4, 6, 10).

USE OF NANOTECHNOLOGY TO INHIBIT BIOFILM FORMATION IN PATHOGENIC BACTERIA

Gholap *et al.* examined the possibility to use nanotechnology to development an agent that inhibits biofilm formation mediated by quorum sensing. They tested a nanocomposite, CdTe-TiO2, using scanning electron microscopy (SEM) and confocal laser scanning microscopy (CLSM) to evaluate biofilm inhibition. SEM analysis showed the exposed cells without the surrounding matrix, while the control showed matrix-covered cells. CLSM showed spatially distributed fluorescence as indication of biofilm inhibition, while the control revealed continuous fluorescence. As a result of CdTe-TiO2 use, the inhibition of biofilm was around 57%. The study also demonstrated that the nanocomposite has antibacterial properties due to formation of reactive oxygen species inside the cells (Gholap H, Patil R, Yadav P et al. CdTe-TiO2 nanocomposite: an impeder of bacterial growth and biofilm. *Nanotechnology* 2013; 24(19):195101).

Department of Pediatrics

CELIAC DISEASE WITH NEUROLOGIC MANIFESTATIONS IN CHILDREN (Abstract): Celiac disease (CD) is an immune-mediated enteropathy triggered by the ingestion of gluten in genetically susceptible individuals and neurologic manifestations may be one of the presentations form. **The aim** of this study was to report the incidence of neurologic manifestations in children with CD. **Material and methods:** Between 2000-2010, 48 children aged 2-18 years diagnosed with CD have been monitored. The diagnosis of CD was made by serological tests and intestinal biopsy. The study protocol included: measurement of weight and height, biological and immunological tests, histological examination, questionnaires filled out by parents about their child motor development and some neurologic signs, psychological exam, electroencephalogram, and brain CT-scan. **Results:** 16 of the 48 children presented one or more neurologic symptoms as the onset manifestation of CD. The neurologic signs in order of frequency were: headache/migraine, attention-deficit/hyperactivity disorder, epileptic seizures, mental retardation, cerebellar ataxia and behavior disorders. Brain CT-scan showed cerebral calcifications in 3 patients with epilepsy, and atrophy in 2 cases with cerebellar ataxia. All children received gluten free diet, but a favorable course was noticed only in the children with migraine and epilepsy, in the other patients this diet having no influence on neurologic symptoms. **Conclusions:** This study proved the variety of neurologic symptoms that can be included in the clinical signs of celiac disease in pediatric patients. That is why in the presence of different neurologic symptoms of unknown etiology and resistant to treatment, celiac disease must be taken into account and laboratory investigations have to include intestinal biopsy and immunological test. **Keywords:** CHILDREN, CELIAC DISEASE, EPILEPTIC SEIZURES, CEREBRAL CALCIFICATIONS, MIGRAINE, SCHOOL PROBLEMS.

Celiac disease (CD) is an immune-mediated enteropathy triggered by the ingestion of gluten in genetically susceptible individuals. Its prevalence is difficult to estimate because many cases are asymptomatic or present atypical signs. The classical form of CD is characterized by gastrointestinal manifestations, including the malabsorption syndrome, steatorrhea, failure to thrive, and histopathological changes (villous atrophy, crypt hyperplasia, lymphocytic inflammatory infiltrate) found in intestinal mucosa biopsy specimens. In the past few years, the clinical spectrum of CD has been widened, atypical forms with late onset or oligosymptomatic being reported. The diagnosis of these forms is made by the identification of antigliadin (IgA-

AGA), antiendomysial (IgA-AEM) and antitissue transglutaminase IgA (IgA-ATTG) antibodies in the blood (1).

The first study on the association of neurologic manifestations in patients diagnosed with BC was published in 1966 by Cooke and Smith (2). The neurologic symptoms appear in 6-10% of the patients with CD, but it was demonstrated that a high percentage of the patients with neurologic signs of unknown cause are also sensitive to gluten (3). The most frequent neurologic symptoms described especially in adults with CD were cerebellar ataxia, epilepsy, myoclonus, neuropathy, dementia, headache, depression and multifocal leucoencephalopathy (2). These symptoms are generally chronic and progressive. At present there are not enough data on the association of neurologic symptoms with gluten sensitivity in children and adolescents.

The aim of this prospective study was to evaluate the neurological manifestations in children diagnosed with CD between 2000-2010.

MATERIAL AND METHODS

The authors conducted this prospective study with the approval of the Hospital Ethics Committee. In this study were enrolled 48 children (27 girls and 21 boys) aged 2 to 18 years who were diagnosed with CD. Informed consent was obtained from their parents. The classical onset symptoms (chronic diarrhea, anorexia, vomiting, and failure to thrive) were present in 32 patients (66% of the cases). The neurologic manifestations were the first sign of CD in 16 cases (33.33%). In all these cases the diagnosis of CD was made by increased IgA-AGA, IgA-ATTG, and IgA-AEM levels and confirmed by intestinal biopsy. IgA deficiency was excluded in all cases.

The study protocol included: physical evaluation; biological and immunological tests; intestinal biopsy with histological exam; questionnaires filled out by parents about motor development and neurologic signs (epileptic seizures, headache, gait disturbances, disorders of limb movement, school problems); neurologic exam; psychological test; electroencephalogram; cerebral CT-scan.

The diagnosis of neurobehavioral conditions, specific learning disabilities, attention-deficit/hyperactivity disorder (ADHD) was based on the diagnostic criteria of Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) (3), the diagnosis of migraine was based on the International Headache Society Classification (4), and the diagnosis of epileptic seizures was based on the 1989 diagnostic criteria of Commission on Classification and Terminology of the International League Against Epilepsy (5).

RESULTS

The spectrum of neurologic manifestations in the 16 patients with atypical CD onset was heterogeneous. Two or more neurologic symptoms were detected in 9 patients (tab. I). In order of frequency the neurologic and psychiatric manifestations were: headache (6 patients), learning disabilities/ADHD (5 patients), epileptic seizures (4 cases), mental retardation (4 cases), cerebellar ataxia (4 cases), and behavior problems (2 cases). All patients received gluten free diet (GFD). A favorable course was noticed only in the patients with epilepsy and headache. GFD had no influence on the neurologic symptoms in 6 children.

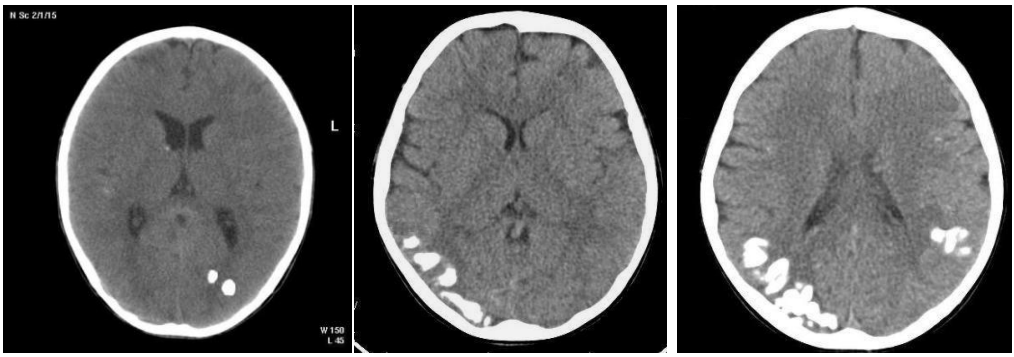
TABLE I

Characteristics of CD patients with neurologic manifestations

Case /sex /age	Neurologic findings	Other clinical symptoms	Delay in CD diagnosis-months)	Serological tests/ histological findings in duodenal biopsy specimens	EEG findings	Brain CT-scan	Course of neurologic symptoms after GFD
1/M 15 years	epileptic seizures	failure to thrive, puberty delay	12 months	anemia, IgA-AGA, moderate villous atrophy	focal discharge	OC	favorable
2/F 11 years	migraine	pallor, fatigue, diarrhea	10 months	anemia, IgA-TTG, partial villous atrophy with crypt hyperplasia	Normal	normal	favorable
3/M 8,2 years	CA, learning disabilities / ADHD	ST, failure to thrive	24 months	anemia, IgA-EMA, villous atrophy with mononuclear submucosal infiltrates	Normal	cerebellar atrophy	no improve-ment
4/M 7,11 years	ADHD	pallor, chronic diarrhea	32 months	anemia, IgA-EMA, villous atrophy with increased IEL	Normal	normal	no improve-ment
5/F 4,3 years	unspecific headache	nausea, loss of appetite, diarrhea	12 months	IgA -AGA, villous atrophy, crypt hyperplasia and increased mitotic index in crypts	Normal	normal	favorable
6/F 14,2 years	migraine	short stature, puberty delay	20 months	IgA- TTG, villous atrophy with submucosal lymphocytic infiltrates	Normal	normal	favorable
7/M 10,4 years	epileptic seizures, SMR	pallor, failure to thrive	22 months	anemia, IgA-AGA, mild villous atrophy, crypt hyperplasia and inflammatory infiltrates in lamina propia	focal discharge	OC	favorable
8/M 7,2 years	MMR, behavior problems	pallor, loss of appetite, altered bowel habits	18 months	anemia, IgA -TTG, villous atrophy with IEL infiltrates	normal	normal	no improve-ment
9/M 16 years	epileptic seizures, ADHD	nausea, loss of appetite, short stature, pallor	23 months	anemia, IgA -EMA, villous atrophy, crypt hyper-plasia and lymphocytic, eosinophilic and basophilic infiltrates in lamina propria	generalized discharge	OPC	favorable
10/M 5,1 years	unspecific headache	none reported	16 months	IgA -EMA, villous atrophy, crypt hyperplasia and IEL infiltrates	normal	normal	favorable
11/F 2,8 years	CA, SMR	nausea, vomiting, diarrhea	12 months	IgA -EMA, partial villous atrophy with increased IEL	normal	cerebellar atrophy	no improve-ment
12/F 17 years	migraine, behavior problems	puberty delay, failure to thrive	16 months	IgA -TTG, villous atrophy, crypt hyperplasia, mononuclear submucosal infiltrates	normal	normal	favorable
13/F 15,9 years	migraine	short stature, puberty delay	10 months	IgA-AGA, partial villous atrophy, crypt hyperplasia	normal	normal	favorable
14/M 9,3 years	ADHD	loss of appetite, diarrhea, pallor	12 months	anemia, IgA -AEM, IgA-AGA, villous atrophy, mononuclear submucosal infiltrates	normal	normal	no improve-ment
15/F 12,8 years	epileptic seizures, ADHD	diarrhea, pallor	14 months	anemia, IgA-AEM, partial villous atrophy, crypt hyper-plasia, IEL infiltrates	generalized discharge	normal	favorable
16/M 4,9 years	CA, MMR	ST	18 months	IgA-EMA,IgA-AGA, villous atrophy, crypt hyperplasia	normal	normal	no improve-ment

CA= cerebellar ataxia, ADHD= attention-deficit/hyperactivity disorder, SMR=severe mental retardation, MMR=moderate mental retardation, ST=steatorrhoea, OC= occipital calcifications, OPC= occipito-parietal calcifications, IEL=intraepithelial lymphocytes

The epileptic seizures preceded the gastrointestinal manifestations in all 4 epilepsy cases. Two of them presented complex partial seizures and the remaining 2 generalized tonic-clonic seizures. Brain CT-scan revealed numerous cortico-subcortical occipital calcifications in cases number 1 (fig. 1a) and 7 (fig. 1b), and occipito-parietal calcifications in case 9 (fig. 1c). Electroencephalogram revealed generalized spike-wave complexes in occipital regions in case 1, parieto-occipital spikes with slow waves in case 7, and generalized spike-wave complexes and polyspikes with great amplitude in occipital derivations in cases 9 and 15. All patients received gluten free diet and treatment with antiepileptic drugs (oxcarbazepine in cases 1 and 7, and sodium valproate in cases 9 and 15). After antiepileptic treatment and gluten free diet these patients had a favorable course without seizures.



1a **1b** **1c**

Fig. 1a. Brain CT-scan case 7: calcifications in left occipital region. **1b**. Brain CT-scan **1c.** Brain CT-scan case 9: numerous bilateral occipito-parietal calcifications case1: numerous cortico-subcortical calcifications in the right occipital region.

Cerebellar syndrome was described in 3 CD patients with a history of neuromotor development delay; one of them presented ADHD and the other two mental retardation. The neurologic exam evidenced disorders of posture (hypotonia), postural instability, gait impairment, disorders of movement coordination. CT-scan revealed cerebellar atrophy in cases number 3 and 11.

Headache was present in 6 CD cases; the diagnostic criteria for migraine were met in cases 2,6,12 and 13, and for unspecific headache in cases 5 and 10. In all patients both the neurologic exam and electroencephalogram were normal. CT-scan was normal in all cases. Jejunal mucosa biopsy confirmed the diagnosis of CD. Patients were fed gluten free diet associated with folic acid and B12 vitamin with favorable course. All children are still monitored, and the repetition of intestinal biopsy confirmed the mucosal recovery. Psychiatric disorders, severe enough to affect the social and occupational functioning of children, were present in 10 CD patients: ADHD/learning problems (5 cases), mental retardation (4 cases), and behavior disorders (2 cases).

DISCUSSION

The neurologic complications are a possible manifestation of CD. The central and

peripheral nervous systems are affected in different degrees (2). According to Collin et al. (6), 16% of the neurologic diseases of unknown etiology represent symptoms of undiagnosed CD.

A higher prevalence of gluten sensitivity was noticed in neuro-degenerative diseases such as hereditary spinocerebellar ataxia and Huntington disease (2). Some studies have reported the onset of CD with extra-gastrointestinal symptoms (7). In our study the neurologic signs were the first symptom of CD in 16 patients. Zelnik (1) reported neurologic complications in 51.4% patients with CD. Briani (9) remarked the association of neurologic manifestations in 22.5% of the 71 patients with CD. On the other hand, Cakir (10) made different neuro-physiological tests in CD pediatric patients and reported subclinical neurologic signs in 11%. In our study 33.33% of children diagnosed with CD presented neurologic symptoms.

The first cases of epilepsy, and intracerebral calcifications associated with CD were described by Gobbi in 1992 (10). Even though the association between epilepsy and CD was just a coincidence, the increasing number of cases reported afterwards in the literature and a higher than expected incidence of BC in patients with epilepsy and intra-cerebral calcifications suggest a correlation. Besides, the progressive growth of intra-cerebral calcifications before de introduction of GFD and the onset of epilepsy with advancing age if CD remains undiagnosed are suggestive of a correlation between these three diseases (11). Some authors claim that the toxicity of gluten may trigger seizures in patients at high risk (1). Diaz et al. (11) believe that all patients with epilepsy and CD must be investigated for CD, even in the absence of digestive symptoms. In our study intracerebral calcifications were evidenced by CT-scan in 3 patients who also presented epileptic seizures. In all patients the association of GFD to antiepileptic medication caused the disappearance of seizures. Some authors consider that in the case of the triple association intracerebral calcifications, epilepsy and CD the favorable response to treatment is possible only if GFD is initiated early (10). Other studies report a good seizure control even if epilepsy was diagnosed after some years of gluten exposure (12).

In Bushara's opinion headache can be an atypical manifestation of CD (2). Some authors suggest that malabsorption is not involved in the pathogenesis of headache crisis in patients with CD, but the inflammatory and autoimmune mechanism may be responsible for its occurrence (1). Roche-Herrero (14) reports the presence of migraine, tension or unspecific headache in 39.5% of children and teenagers with CD. In our study 6 of the 48 patients presented headache. In all the cases the initiation of GFD determined the disappearance of migraine and headache episodes.

Many authors reported the presence of cerebellar ataxia in CD patients (14). There are studies that report an increased incidence of CD and sensitivity to gluten in patients with idiopathic cerebellar ataxia (15). Also, some authors noticed cerebellar symptoms in patients with CD (1,14). Zelnik (1) diagnosed intracerebral calcifications in 10.25% of the patients with CD, and in our study 3 of 48 patients with CD presented signs of cerebellar ataxia.

Developmental delay is relatively frequent in the history of children with CD, in our study being found in 3 children with cerebellar ataxia and CD, probably due to

nutritional deficiencies and toxic effects of severe malnutrition.

Psychiatric signs may be frequent in CD patients. Rodrigo (16) claims that these symptoms may be present in about 1/3 of the cases. In the study of 111 patients with CD, Zelnik (1) noticed the learning and behavior problems in 20.7%. In our study 10 of the 48 cases presented a delay in mental development, ADHD, learning and behavior problems, these data being comparable with those reported in the literature.

The mechanism by which gluten intolerance contributes to the occurrence of neurologic manifestations remains unclear. It is supposed that the pathogenic mechanism of neurologic and psychiatric manifestations associated with CD is determined by the toxic effects of gluten or an immune reaction initiated by gluten or its metabolites in the intestinal mucosa, as well as the severe and prolonged lack of thiamine, pyridoxine, ciancobalamine (due malabsorption) and folic acid deficit (14). Some authors believe that the toxicity of gluten induces by an autoimmune mechanism irreversible lesions of vasculitis, inflammatory lesions and lymphocytic infiltrates at neuronal, glial and axonal level, reason why the clinical picture is minimally improved by GFD, and the disappearance of different antibodies in blood or cerebrospinal fluid (2).

The identification of the same phenotype HLA (DQW2DR3 and/or DR7) in patients with neurologic manifestations suggests immune system disturbances (2).

The authors who have used GFD in patients with CD and neurologic symptoms reported very different results. Siqueira stated that such a diet does not improve the neurologic symptoms (7). On the other hand, Diaz reported a favorable course after GFD in patients with CD and epilepsy (11). In our study the GFD gave good results in cases number 2, 5, 6, 10, 12 and 13 who presented migraine and headache episodes.

CONCLUSIONS

Neurologic and psychiatric symptoms may be present not only in some diseases primarily affecting the brain, but also in gastrointestinal diseases, in our case CD. That is why, CD must be considered in patients with different neurologic symptoms of unknown etiology that are resistant to treatment, because in many cases CD types are atypical, monosymptomatic or latent. In all these situations the laboratory investigations will necessarily include intestinal biopsy and immunological tests, and in patients with confirmed diagnosis GFD will be initiated, even though GFD does not always influence in a favorable way the course of neurologic symptoms.

NEWS

IDENTIFICATION OF PERMETHRIN RESISTANCE LOCI IN MALARIA VECTORS

Resistance to the limited insecticides used for malaria control is a growing threat, thus, identification of the major loci responsible for resistance is in need. Witzig and co. used quantitative trait loci (QTL) mapping to identify resistance phenotypes in the major malaria vector, *Anopheles gambiae*. The study shows the results of mapping of pyrethroid resistance in 3 isofemale pedigrees established from wild *A. gambiae* and makes suggestions for future genetic mapping of insecticide resistance. Two QTL were identified on chromosomes 2L and 3R, in similar genomic sites as those previously identified in laboratory strains (Witzig C, Wondji CS, Strode C, Djouaka R, Ranson H. Identifying permethrin resistance loci in malaria vectors by genetic mapping. *Parasitology*. 2013;28:1-10). [Epub ahead of print])

EFFICACY OF RIFAXIMIN VERSUS LACTULOSE FOR REDUCING THE RECURRENCE OF OVERT HEPATIC ENCEPHALOPATHY AND HOSPITALIZATIONS IN CIRRHOSIS (Abstract): Both rifaximin and lactulose have been reported to be effective for maintenance of remission from hepatic encephalopathy (HE) in patients with cirrhosis. The **aim** of this study was to compare the efficacy of different treatment strategies for preventing recurrences and HE-related hospitalizations. **Materials and methods:** Seventy-eight cirrhotic patients who recovered from HE were grouped according to one of the following therapies: rifaximin intermittently 14 days/month (RI- group), rifaximin 400 mg three times daily (RD-group) and lactulose 30 to 60 ml in 2 or 3 divided doses daily (L-group) for a 6-month period. The follow-up lasted 12 months. A Kaplan-Meier analysis was performed to determine the probability of developing recurrent overt HE episodes. The frequencies of HE- related hospitalizations in the three groups were evaluated comparatively. **Results:** Over a 12-month follow-up period, 10 (26.31 %) of 38 patients in the RI-group, 7 (25%) of 28 in the RD-group and 4 (33.33 %) of 12 in the L-group experienced recurrent bouts of HE, the differences not being significant. More L-group patients experienced more severe episodes of overt HE in spite of mild or moderate disease. In the rifaximin groups overt HE episodes were similarly frequent, and the severity of bouts was associated with Child-Pugh score. Fewer hospitalizations were reported in the rifaximin groups. **Conclusions:** According to our data, rifaximin and lactulose are equally effective for the maintenance of remission from overt HE. However, rifaximin is superior for reducing the risk of HE-related hospitalization. **Keywords**: HEPATIC ENCEPHALOPATHY, LACTULOSE, RIFAXIMIN, HOSPITALIZATION.

Hepatic encephalopathy (HE) is a common complication of either acute or chronic liver disease, potentially reversible, or progressive. The annual risk of developing overt HE in cirrhotic patients is 20% (1). An estimated one-third to one-half of hospitalizations for cirrhosis are related to overt HE, and the frequency of hospitalization for overt HE has nearly doubled over the last decade.

HE is characterized by disturbances in consciousness and behavior, personality changes, fluctuating neurological signs, as-

terixis, and electroencephalographic changes (2). The neuropsychiatric abnormalities range from cognitive deficits (referred to as subclinical HE, minimal HE, or more recently, covert HE), which can only be diagnosed by specialized testing to clinically apparent neuropsychiatric complications consisting of alterations in consciousness and motor disturbances (referred to as overt HE) (3, 4).

Gut-derived toxins such as ammonia are thought to play a central role in the pathogenesis of HE (5). Treatment strategies are based on the principle of reducing the production and absorption of ammonia in the gut.

The development of HE is considered a sign of a poor prognosis and patients should receive therapy for an indefinite period of time or until they undergo liver transplantation (6). Therefore, prevention of overt HE is warranted. The term secondary prophylaxis was proposed to define the therapy administered to prevent recurrence of overt HE in patients with a history of overt HE episodes (7). Currently, the options for a long-term treatment of HE are lactulose, a non-absorbable disaccharide, and rifaximin, a minimally absorbed oral antibiotic. Several studies have demonstrated the efficacy of rifaximin and lactulose for the maintenance of remission from HE and decrease in hospitalization requirement (7, 8).

In this prospective study conducted over a 12- month period we evaluated comparatively the efficacy of rifaximin and lactulose for prevention of overt HE recurrence and frequency of HE-related hospitalizations in patients with previous episodes of overt HE.

MATERIAL AND METHODS

Patients with cirrhosis who were followed up in our outpatient clinic or hospitalized between October 2010 and December 2011 were considered eligible. The study was performed in accordance with the ethical principles of the Declaration of Helsinki. The protocol was explained to at least one relative of each patient and written informed consent was obtained from all selected patients or their relatives.

Inclusion criteria were: patients with a definite diagnosis of cirrhosis, at least one episode of overt HE in the history (grade 2 or more according to West-Haven criteria) and remission at baseline (grade 0 or 1 according to West-Haven criteria), different grades of liver failure (Child-Pugh A-C, MELD 10-25), and a written informed consent to participate. Exclusion criteria were: gastrointestinal bleeding, spontaneous bacterial peritonitis or other conditions associated with HE precipitation within 3 months before the enrollment, diagnosis of a neurological or psychiatric disease, and current use of psychotropic medications, systemic uncontrolled disease (cardiac, respiratory, kidney failure), recent (< 3 months) active alcoholism, and absence of informed consent. Seventy-eight patients were evaluated. There were no significant differences in the distribution according to gender and etiology of the cirrhosis. Most patients had mild to moderate liver failure. Esophageal varices 2nd degree or more were detected in 54 of the 78 patients (tab. I).

Before enrollment, all patients had a score 0 or 1 according to West-Haven scale.

In order to evaluate the efficacy of different treatment strategies our patients were divided into three groups. RI Group = 38 patients (48.8%) was treated with rifaximin intermittently (14 days/month for 6 months), RD Group = 28 patients (35.9%) received rifaximin daily (400 mg three times daily), and L Group= 12 patients

(15.3%) treated with lactulose 30 to 60 ml in 2 or 3 divided doses per day, for a 6-month period. No significant differences in terms of age, gender, etiology of cirrhosis and severity of liver disease were found in the three groups.

TABLE I
Patients characteristics

CHARACTERISTIC	
Age (yrs)	56.3 [41-75]
Gender (M/F)	44/34
Etiology of cirrhosis:	
Alcoholic	29
HCV/HBV/HBV+HDV	37/2/4
HCV+alcohol	6
MELD score	15.69 [10-25]
Child-Pugh class (A/B/C)	27/43/8
Esophageal varices (No/I/II/III/IV)	20/38/12/4

All patients were followed up every 3 months or at any presentation in outpatient clinic or hospital in a period of one year. Patents were monitored for occurrence of recurrent overt HE, the incidence and severity of episodes and number of hospitalizations involving any episode of overt HE being recorded.

HE was assessed using West-Haven mental status scale and asterixis grade. West-Haven criteria are defined as follows: grade 0: no detectable changes in behavior or personality; grade 1: trivial loss of awareness, euphoria or anxiety, shortened attention span, impaired performance of addition; grade 2: lethargy or apathy, impaired performance of subtraction, minimal disorientation to time or place, subtle personality change, inappropriate behavior; grade 3: confusion, gross disorientation, somnolence to semi-stupor(may respond to verbal stimuli); and grade 4: coma (no response to verbal or noxious stimuli) (9). Asterixis was graded as follows: 0, no tremors; 1, few flapping motions; 2, occasional flapping motions; 3, frequent flapping motions; and 4, almost continuous flapping motions (10).

An episode of overt HE was defined as an increase from a baseline West-Haven score 0 or 1 to a score of 2 or more, or baseline West-Haven score and asterixis grade each increasing by 1 point. HE–related hospitalization was defined as hospitalization directly caused by HE or a hospitalization during which a HE event occurred.

RESULTS

Recurrence of overt HE

Of the 78 patients, overt HE episodes occurred in 21 (26.92%) during the 12-month study period. The distribution of total cases of overt HE was as follows: 10 of 38 patients in RI group, 7 of 28 patients in RD group and 4 of 12 patients in L group. Probability of developing recurrent overt HE, illustrated by a Kaplan-Meier analysis, was not significantly different in the three groups: 26.31% in RI group, 25% in RD group versus 33.33% in L group (fig. 1).

Severity of the overt HE episodes

Patients in L group experienced more

severe episodes of overt HE (grade 3/4) in spite of mild or moderate disease. In the rifaximin groups overt HE episodes were similarly frequent and associated with the severity of liver disease according to Child-Pugh score.

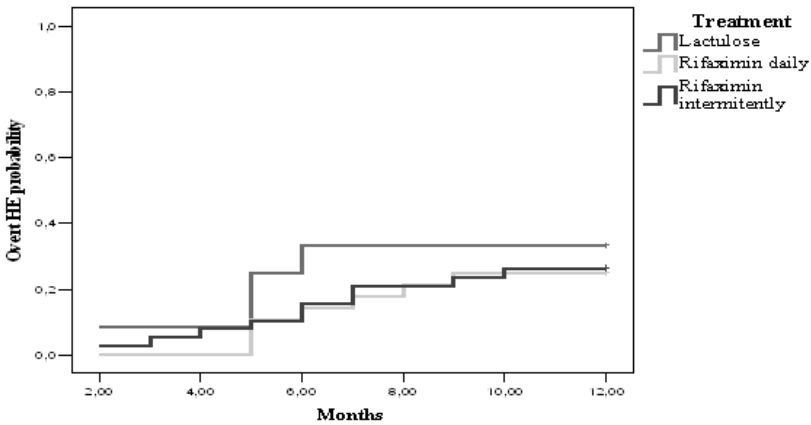

Fig. 1. Probability of developing recurrent overt HE in patients receiving therapy with lactulose following an episode of overt HE compared with patients receiving daily or intermittently rifaximin.

Safety

No serious adverse events related to either treatment were found during the study. There was no significant difference between rifaximin and lactulose on overall patient compliance (100% versus 92%). The most common adverse events with rifaximin were abdominal pain (5 patients-7.57%) and dizziness (3 patients-) showing no consistent pattern or dose relationship. In the lactulose group, 2 patients (16.66%) complained of abdominal pain and 4 patients (33.33%) experienced diarrhea.

TABLE II

Requirement for EH-related hospitalization

Number of EH-related hospitalizations	Rifaximin intermittently group (10 patients)	Rifaximin daily group (7 patients)	Lactulose group (4 patients)
Overall	**12**	**8**	**6**
One admission	8	6	2
Two admissions	2	1	2

Hospitalizations

A total number of 26 HE-related hospitalizations were recorded during follow-up. The 10 patients in RI group required 12 hospitalizations: two patients required two hospitalizations and eight patients one hospitalization. The 7 patients in RD group required 8 hospitalizations: one patient two admissions and six patients one. In the L group, the 4 patients experienced 10 hospi-

talizations: two patients one admission and two patients two admissions (tab. II). The frequency of HE-related hospitalization was comparable between RI group and RD group (31.57% *vs.* 28.57%), but significantly lower than in L group (50%).

DISCUSSION

Recurrent bouts of HE that require evaluation and hospitalization cause a significant burden to patients, their families and caregivers as well as to the healthcare system.

Currently, lactulose and non-absorbable antibiotics such as rifaximin are the only two medications effective when used for secondary prophylaxis against recurrence of overt HE in patients who have recovered from an episode of overt HE (7, 8, 10).

Systematic reviews of randomized trials comparing disaccharides *vs.* antibiotics for the treatment of HE has shown contradictory results. Whilst Nielsen et al. found superior outcomes with the use of antibiotic therapy (11), a meta-analysis of seven randomized controlled trials concluded that rifaximin was not superior to non-absorbable disaccharides in the long-term or short-term treatment except that it was better tolerated (12). Recently, another meta-analysis found that rifaximin has similar effectiveness to other oral therapies with a better safety profile (13).

Both rifaximin and lactulose demonstrate superior efficacy versus placebo for maintenance of remission from HE and lowering the frequency of HE-related hospitalizations. Sharma et al.(7) published the results of a recent open-label study of lactulose versus placebo for preventing recurrence of overt HE in cirrhotic patients showing the utility of lactulose as a secondary prophylactic therapy. Over a median follow-up period of 14 months, the probability of developing recurrent overt HE in patients receiving lactulose was 19.6% compared with 46.8% in the placebo group. Bass et al.(10) found rifaximin 550 mg twice daily more effective than placebo for maintenance of remission from HE over a 6 month period (rifaximin 22% breakthrough HE episodes versus placebo 46%). Further evaluation in a 24 months open-label maintenance trial concluded that long term treatment with rifaximin provide continued protection from HE and reduce the hospitalization rate (8). One of the main limitations of the study was the lack of a real placebo group, concomitant administration of lactulose being permitted. Hence this limited the evaluation of the efficacy of rifaximin alone.

Our study confirmed the efficacy of the two drugs in the maintenance of remission from overt HE, in agreement with the published data (7, 8, 10). Lower frequencies of HE hospitalizations were observed in the rifaximin groups, in line with the results of retrospective chart reviews (14, 15), which have shown that rifaximin, as compared with lactulose, is associated with a significantly lower rate and duration of hospitalization and lower hospital costs. We found a better tolerability of rifaximin which coincides with previous data (14, 16). However, our results are in contradiction with a recent meta-analysis which reported no significant difference between rifaximin and lactulose on diarrhea, but a significant difference in favor of rifaximin on abdominal pain (12).

It appears that rifaximin monotherapy could be a suitable option for long term treatment. However, given the high treatment cost and the current available data, it may be prudent not to recommend rifaximin as long

term treatment in all cirrhotic patients. Our results could represent a starting point for evaluating in future studies the cost-effectiveness and budget impact of competing therapies in hepatic encephalopathy.

The current study differs from the previous randomized studies in that it compared rifaximin and lactulose in terms of prevention the recurrences of overt HE and HE-hospitalizations; we did not have a placebo group since the lack of the treatment in patients at high risk for hepatic encephalopathy was considered unethical. In addition, we evaluated two dosage regimens for rifaximin (daily/intermittent) which proved to be similar for secondary HE prophylaxis. As in a previous study, we chose to define remission as West-Haven grade 0 or 1 because of the difficulties and variability in diagnosing mild HE, in addition with a known fluctuating course between 0 and 1.

One limit of our study is related to the small number of enrolled patients. Also patients with highly advanced liver disease (MELD score >25) were not evaluated.

CONCLUSIONS

We demonstrated that over a 12-month period, rifaximin in daily or intermittently dosage and lactulose are effective in the prevention of overt HE recurrences. No marked difference between the three therapeutic regimens was found in terms of maintenance of remission from overt HE. However, rifaximin reduces the risk of hospitalization involving HE better than lactulose.

NEWS

EFFECT OF LAYERING METHODS, COMPOSITE TYPE, AND FLOWABLE LINER ON THE POLYMERIZATION SHRINKAGE STRESS OF LIGHT CURED COMPOSITES

The polymerization shrinkage and its associated stress still remain a major drawback of dental composite materials, resulting in bond failure, cuspal flexure, enamel microcracking and bacterial infiltration. Different materials and techniques have been suggested to minimize shrinkage stress of composite resins. The aim of this study was to investigate the effect of layering methods, flowable composite liner and use of low shrinkage silorane-based composite on the polymerization shrinkage stress of light cured composites. Aluminum blocks were used to prepare MOD cavities and divided into four groups. A universal hybrid methacrylate-based composite (Z250), a flowable composite (Z350 flowable), and a silorane-based composite (P90) were used to fill the cavities. Cavities were restored using the bulk technique with Z250, an increment technique with Z250, an increment technique with Z250 and a Z350 flowable lining, and an increment technique with P90. The axial shrinkage strain and flexural modulus of the three composites were determined, and cuspal deflection of each group was measured with linear variable differential transformer probes and compared among groups using ANOVA and Tukey's post hoc test ($\alpha = 0.05$). The incremental filling technique yielded significantly lower cuspal deflection than the bulk filling technique. Flowable composite lining under universal composite (Z250) layering showed higher cuspal deflection than that without flowable composite lining. Silorane-based (P90) composite exhibited lower cuspal deflection than metacrylate based (Z250) composite. These results suggest that cuspal deflection resulting from polymerization shrinkage stress may be reduced by an incremental filling technique and by the use of low shrinking composite. On the other hand, flowable composite lining under conventional composite layering dd not reduce the polymerization shrinkage stress in this study. The cuspal deflection of the first increment layered with a flowable composite liner (Z350 flowable) was considerably higher than the first increment layered with a conventional hybrid composite (Z250). However, the authors suggest that using flowable composite liners with different elastic modulus, shrinkage values, and varying thickness might produce different results (Kwon Y, Ferracane J. Effect of layering methods, composite type, and flowable liner on the polymerization shrinkage stress of light cured composites. *Dental Materials* 2012; 28(7): 801-809).

RISK FACTORS AND THEIR IMPLICATIONS IN THE EPIDEMIOLOGY OF PEDIATRIC OBESITY (Abstract): Obesity is the most common food disorder in children from developed countries, its frequency alarmingly increasing in Romania. **Aim:** To evaluate the epidemiological dynamics of obesity and associated risk factors. **Material and methods:** Retrospective and prospective study of 146 obese children admitted to the 2nd Iasi Pediatric Clinic between 2008-2012 aimed at evaluating the epidemiological dynamics of obesity and associated risk factors. Most subjects were teenagers (33%), followed by school age children (21%). **Results:** A growing tendency towards obesity in the study children was noticed during the 5-year follow up. Genetic factors, short breastfeeding, early onset of obesity, and eating disorders were the main obesity-associated risk factors, along with obesity in 1st degree relatives. **Conclusions:** Early infantile and juvenile obesity remains a medical and social problem in our geographic area, and unfortunately a neglected reality. Genetic factors, absence of breastfeeding, inappropriate food habits in the early years of life lead to permanent disorders, with serious consequences in adult life. **Key words**: OBESITY, CHILDREN, RISK FACTORS.

In the last century, there were major changes in the epidemiology of obesity: thus, if between 1950 and 1960 this condition occurred at older ages in Western and some Northern European countries, now its spread is pandemic, reason why scientists have named it "globesity". It has become the main health problem of the 21st century (1, 2), mostly in the United States, population studies demonstrating the increasing prevalence of overweight and obesity in children.

Epidemiological data of pediatric obesity worldwide

Approximately 50% of the obese children grow up to become obese adults. WHO expectations for 2025 are over 300 million obese people worldwide (1). In Australia, China, Brazil, and United States, the growth rate of pediatric obesity highly exceeds that of adult obesity.

According to the NHANES study (1963-1995), the number of obese patients has doubled, increasing by 40% in the age group 12-17 years and by 54% in children aged 6-11 years. Prevalence of overweight in adolescents increased from 5% to 10.5%, and in children aged 6-11 from 6.5% to 11.3%. In the US, 1 of 4 children aged 6 to 17 years and 1 of 2 adults are overweight,

10% of preschool children are obese, many with decreased glucose tolerance (3). During the last two years, over 30% of the American children became obese, doubling the estimated percentage. The prevalence of obesity in the 6-14 years age group is increasing, from 4% during 1963-1965 to 13% in 1999, and in adolescents aged 12-19 years from 5% (1966-1970), to 14% in 1999 (4). Prevalence is growing rapidly being now 50% higher than in 1960. International Association for the Study of Obesity (IASO) estimated that, worldwide, 10% of school children, that is 120 millions, are overweight or obese. According to WHO, globally, obesity has exceeded the prevalence of malnutrition, 15-18% of children being affected by overweight and obesity. Clinical studies showed an increased prevalence of the metabolic syndrome associated with ageing (5,6), but also found in childhood.

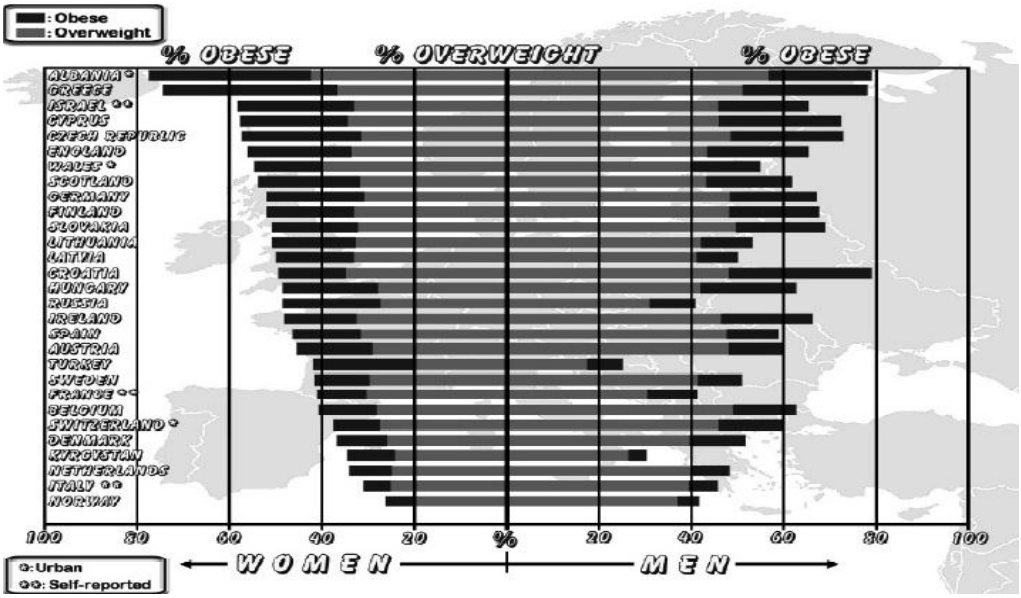

Fig. 1. Prevalence of obesity and overweight in Europe (IOFT, October 2008).

At the end of the last decade, International Obesity Task Force (IOTF) was commissioned by WHO to coordinate anti-obesity measures worldwide and to submit a report on the prevention and management of global obesity (fig. 1).

In 2004-2005, in Iran an epidemiologic study on obesity was conducted in subjects aged 15 to 65 years; the aim was to estimate the prevalence of overweight in that area and to predict the future obesity rate. The results pointed out that the prevalence of overweight and obesity was 57% in women and 42.8% in males; underweight was 5.2% in women and 6.3% in male population (7). In Mexico, there was an increase of 50% of obesity prevalence in children and adults in the last ten years. The highest prevalence of overweight and obesity was reported in the Pacific Islands and Saudi Arabia. According to NHANES II study (1976-1980) there is an increased prevalence of overweight in all age groups: 2-5 years (preschool children), from 5% to

12.4%, 6-11 years, from 6.5% to 17%, and 12-19 years, from 5% to 17.6% (8). More recent data (NHANES 2003-2006) show a higher prevalence of obesity in the boys aged 12 -19 years (27.7%) than in age-matched girls (19.9%). African American and Hispanic children have a higher risk for developing overweight compared to Caucasian children. In 2008, the prevalence of obesity increased in children of American Indian. Alaskan native (21.2%) and Hispanic (18.5%) children, and decreased in Asian children (12.6%) (9). Even in developing countries there was an increased prevalence of obesity in children under 5 years, from 12.4% in 1998 to 14.5% in 2003 and only to 14.6% in 2008. The incidence is still increasing in all age groups including infants and preschool children. In England, childhood obesity rate is 7 %, and infantile obesity rate 27.7%. In the U.S., the frequency in preschool, and school children and teenagers is of 14.1%, 3-20% and 10-30%, respectively. In Chile, studies showed that 7% of preschool and 12% of school children are obese. In many other countries, more than half of people are overweight and obese. It is estimated that 97 million U.S. adults are overweight or obese. Most of them were obese as children. In the past decade, the prevalence of obesity increased by almost 40% in most European countries, especially in the male population (10) (fig. 2). Currently, it is estimated that about one quarter of the world's population is overweight before the age of 20 years, and half will be obese by the age of 20. In 2000, in France, 16% of the children aged 5 to 16 years were obese, and in Italy 25% (6, 11).

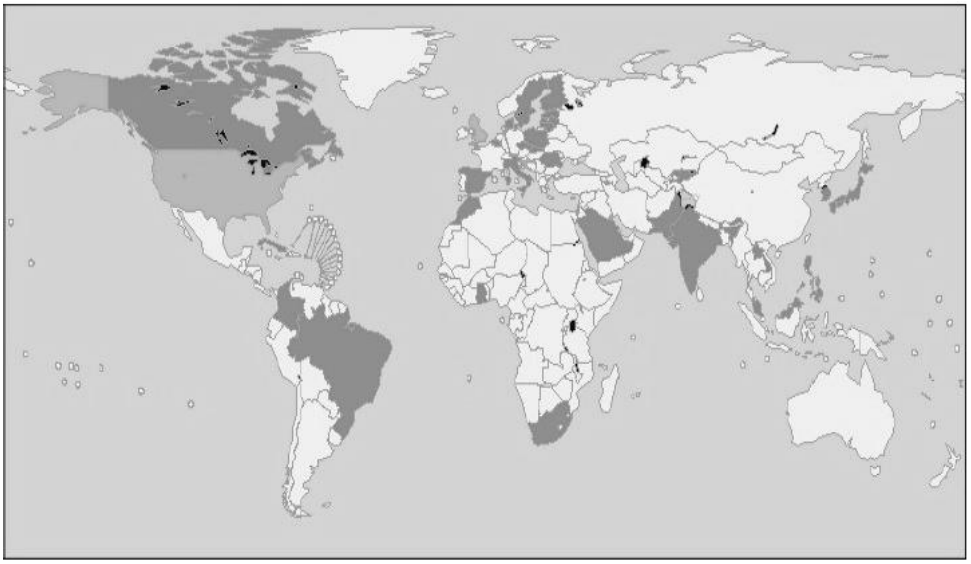

Fig. 2. Prevalence of obesity (WHO, April 2008). Legend: Open white areas - lack of data, gray areas - the prevalence of 30-40% black areas – prevalence over >40%.

In Europe, childhood obesity has tripled in the past 20 years; in the Mediterranean and Eastern Europe countries, up to 40% of the women were obese In Western European countries, obesity is about 25%, in Northern Europe the prevalence of overweight chil-

dren is 10-20%, while in the Southern countries it is 35% and is increasing. It is alarming that the onset of overweight and obesity is at a young age, and in certain geographical areas, some preschool children have decreased glucose tolerance, being at higher risk for type 2 diabetes. The highest prevalence was recorded in Malta (31% boys and 28% in girls) and the lowest in Lithuania (10.3% boys and 4.7% in girls). In Belgium, between 1980 and 1990, the prevalence of obesity increased from 9.2% to 14.5% (12). Reports of the International Obesity Task Force (IOTF) showed the same trend in Southern Europe, where 1 out of 10 children are overweight. In England (1999), the prevalence of overweight increased from 22% at age 6, to 31% at 15 years, and obesity from 10% to 17% in the same age ranges (13). In Germany, a 20 year-study (1975-1995) showed an increase in overweight from 10% to 16.3%, more common in girls, and in obesity from 5.3% to 8.2 % (9).

In France, a study conducted in children in the interval 2000-2001 showed a 3.8% prevalence of obesity and overweight of 3.8% and 14%, respectively (8). An Italian study (2000 – 2002) reported a higher prevalence of overweight of 27.2% in boys and 29.5% in girls aged 6 to 11 years, and obesity of 6.5% in boys and 7% in girls. Recent studies show that in Italy 36% of the 9-year-old children are overweighed or obese, while in Greece the prevalence is 19% in the age group 6-17 years (14). In Spain, 27% of children and adolescents are obese. Epidemiologic studies carried out in the interval 1998-2000 showed a prevalence of overweight of 31.4% in boys and 32.4% in girls, and of obesity of 10.4% and 10.2% in boys and girls, respectively.. Between 1998 and 2004, Bulgaria reported an increase in the prevalence of overweight from 19% to 22% in boys and from 16% to 18% in girls (15).

Obesity in Romanian children

There are few studies on obesity in Romanian children. In 1980, a group of children from 3 months to 16 years of age from Western Romania was measured for assessing the nutritional status; 14.7% were identified to be obese, with a slightly higher frequency of school-age girls. In the 5250 children, obesity had a prevalence of 18.62% in infants, 15.05% in preschool children, and 14.20% in school-age children (4). "Alfred Rusescu" Institute for Mother and Child Care (IOMC) in Bucharest launched the National Nutritional Surveillance Program (1993-2002). The epidemiological studies showed a prevalence of overweight in children aged 0 - 4 years of 6.4% in girls and 5.5% in boys. In 2008, in Cluj-Napoca, a study on 7904 schoolchildren, reported a prevalence of overweight of 12.8% and of obesity of 8.2%. The highest prevalence was recorded in the age group 6-10 years, both for overweight - 15.9%, and obesity-13.3%, and the lowest prevalence in adolescents: 7.6% for overweight and 3.8% for obesity (16).

Risk factors that need to be identified and avoided

Although the risk factors for obesity are clearly represented by heredity (90%), there are many phenomena that target feeding behavior, regulation of appetite and bad eating habits, which can be identified and avoided. Some authors noted that early adiposity rebound (at 3 years of age), high birth weight or prematurity (with a subsequent rapid growth rate), lack of physical activity, correlated with the occurrence of early obesity, The earlier the rebound is, the higher the adiposity will be at adult

age. Thus, dynamic assessment and recording of BMI rebound may allow initiation of preventive measures. Rapid weight gain in the first six months of life is a predictor factor for developing obesity by the age of 3 years (17). Avoiding obesity both before pregnancy and after delivery is crucial for the future baby weight. Low birth weight for gestational age associated with a rapid weight gain after birth increases the risk of obesity, metabolic syndrome and diabetes. Newborns of obese mothers are often overweight and they can develop obesity on long term basis. Children with higher gestational age because of maternal insulin resistance and decreased glucose tolerance are at risk for obesity. Positive family history for obesity and early onset of overweight increase the risk of obesity up to 80% for those with both parents obese and up to 40% for children with one obese parent. Rapid weight gain during the first 4-6 months is associated with higher risk of childhood obesity and with its abdominal distribution in children (18). Breastfeeding should be recommended as a protective factor against obesity in adolescence. The risk of obesity decreases proportionally with the duration of breastfeeding (up to 9 months), each month of breastfeeding decreasing by 4% the risk of obesity. Artificial feeding and excess protein intake in the first year of life are considered risk factors for subsequent development of obesity, with pancreatic and kidney overload. Cow milk proteins specifically stimulate massive IGF-1 release (19). Impaired nutrition in pregnant woman has an important role in childhood obesity and its impact involves some risk factors such as: low birth weight, increased amount of insulin in the amniotic fluid, hypothalamic activity, stimulating and inhibitory peptides. The relationship between obesity and age involves alteration of appetite regulating systems (hunger/satiety balance), which develop in pregnancy and neonatal period. Fetal and neonatal life are critical for the maturation of the complex systems involved in the pathology of metabolic syndrome and obesity. Fetal malnutrition is the result of maternal malnutrition, placental insufficiency, which can add more maternal abnormalities. This leads from low birth weight to later overweight and therefore to obese adult. It has been suggested that genes play an important role, parental obesity being a major risk factor for childhood obesity (17).

MATERIALS AND METHODS

In this study, the authors evaluated a group of patients admitted to the Iasi " St. Mary" Children Hospital in the interval 2008-2012. The aim was to investigate retro-prospectively the epidemiological dynamic of obesity, age-group distribution, and the main risk factors involved in its occurrence.

RESULTS AND DISCUSSION

The study showed an annual increase in the incidence of obesity; thus, during the 52-month study interval, 146 new cases of obesity were detected. (fig. 3). Most children were from urban areas (77%) and 58 patients had first degree relatives with obesity.

Age-distribution of the cases revealed a high obesity rate in teenagers (one third of the cases), with long-term severe consequences, followed by school-age and preschool children (8% of the study patients were obese infants) (fig. 4).

Most study children were from urban areas (71%), with some well-known predisposing factors: less strict meal plan, access to "fast food", large amounts of refined sugar consumption, and reduced

levels of physical activity. By contrast, rural area children had a more balanced diet, with a higher intake of fresh fruits and vegetables, along with more types of physical activity, (residential houses with a backyard, household and farming activities, entertaining activities).

History of the first year of life showed that one third of the children were not breastfed, and 15% were breastfed for a short period of time, because of low milk supply, early resumption of professional activity, appetite and satisfying weight gain after baby food diversification (fig. 5).

CONCLUSIONS

Childhood and juvenile obesity remain an important medical and social problem worldwide, sadly an ignored reality. The major risk factors are food behavior, poor breakfast, heavy dinner, low fiber diet, lack of exercise. The onset is earlier and more obvious for overweight, as breastfeeding duration is shorter, so young mothers should be encouraged to breastfeed for a longer period despite some minor inconveniences. The higher the prevalence of obesity in the general population, the higher the health system costs. Implementation of prevention and curative measures will have a major impact on this epidemiological phenomenon and expansion of obesity worldwide.

DISCHARTHROSIS WITH HYPERALGIC LUMBAR MULTILEVELED RADICULAR SYNDROME (Abstract): The problems at the level of intervertebral discs are producing dysfunctions and important functional regression at the level of lumbar column, at a stage at which the patient could remain blocked in an anterior or lateral flexion position or producing an antalgic position of scoliosis that could incapacitate the patient to perform activities of daily living. The medical rehabilitation, in such cases, must seek not only the relief of local pain through different methods of obtaining it, but also the functional reeducation of the intervertebral articulations through specific analytical mobilization in order to achieve the biomechanical harmonization of the rachis. **Material and methods**: We report the case study of a 66 year-old patient who presented to our clinic for medical consult and physical therapy when he was diagnosed with discharthrosis, hyperalgic lumbar multileveled radiculopathy at L4 – L5 and L5 – S1. The lumbar x-ray showed osteophytes, disc narrowing at the level of L5 – S1 and inter-apophysis arthrosis. The clinical examination revealed difficulty walking with pain in the right sacroiliac articulations and right sciatic emergence with plantar paraesthesia. The patient developed pain induced scoliosis on the right side that restricted the lumbar range of motion and prevented the right flexion blocking him into an left flexion, any attempt of straightening inducing pain. The condition was treated using specific analytical lumbar mobilization for the realignment of the vertebrae complex. **Conclusions**: In this case study, we found that functional reeducation in cases of pain induced deviations of the rachis of the column should be centered on the harmonization of inadequate pressure and position of the complex intervertebral articulations. **Key words:** FUNCTIONAL REEDUCATION, LUMBAR DISCOPATHY, DISCHARTHROSIS, RADICULAR SINDROM, ANALYTICAL MOBILIZATION

Problemele discale lombare produc disfuncţionalităţi şi restanţe funcţionale importante la nivelul mobilităţii coloanei lombare, pacienţii putând rămâne blocaţi în diferite grade de anteroflexie şi lateroflexie sau scolioze antalgice neredresate ducând la incapacitatea efectuării ADL-urilor (*Activities of Daily Living*) (1). Recuperarea medicală în astfel de situaţii trebuie să-şi îndrepte atenţia nu numai spre îndepărtarea durerii locale, prin diferite metode de analgezie ci şi spre o reeducare funcţională discală, şi articulară prin manevre specifice, cu posibilităţi de rearmonizare a com-

plexului biomecanic al rahisului (2). Studiul de caz prezentat vine să sublinieze importanța refacerii mobilității analitice a coloanei lombare.

MATERIAL ŞI METODE

Pacientul S. V. în vârstă de 66 ani de sex masculin, din mediu urban, s-a prezentat la Centrul de Fiziokinetoterapie şi Recuperare pentru consult şi tratament de specialitate unde a fost diagnosticat cu discartroză, sindrom radicular hiperalgic lombar etajat la nivelul L4 – L5 si L5 – S1 şi tulburări de statică vertebrală. Examenul radiologic toraco-lombar a evidențiat osteofite dorso-lombare cu pensare discală la nivel L5 – S1, punți osoase marginale, scleroza platourilor corpilor vertebrali lombari, importantă artroză interapofizară şi interspinoasă lombară, cu accentuarea lordozei lombare şi articulații sacroiliace şterse bilateral. Examenul clinic a evidențiat un mers posibil sprijinit cu bastonul pe partea stângă, foarte dificil pe călcâi şi pe vârfuri, cu o mică dificultate în stațiune bipodală. Mersul se executa cu dureri în articulațiile sacro-iliace bilaterale, cu precădere pe partea dreaptă şi algii la palparea emergenței sciatice drepte, cu parestezii la nivel plantar, predominant pe partea dreaptă. Coloana vertebrală prezenta în regiunea dorsală o scolioză dextroconvexă cu sensibilitate la palparea apofizelor spinoase cervico-dorso-lombare. Testul Schöber edificator pentru mobilitatea coloanei lombare a fost de 10/11,5cm pacientul prezentând o lateroflexie sever limitată spre partea dreaptă.

DISCUȚII

Tratamentul fizical-kinetic s-a desfăşurat pe durata a 20 de şedințe şi a avut drept obiectiv realizarea analgeziei locale, refacerea staticii, ameliorarea mobilității coloanei şi a constat în electroterapie de tip TENS premodulat hiperalgic, pe zona coloanei lombare, laser pe articulațiile sacroiliace drepte, masaj terapeutic, kinetoterapie individuală şi mobilizări articulare specifice lombare. După 5 şedințe de terapie mobilitatea coloanei lombare pe flexia anterioară a crescut fiind evidențiată prin testul Schöber 10/15cm, iar durerea fiind evaluată pe scara EVA (0-10) la 2. Pacientul nu a mai invocat nici un fel de durere la nivel de anteroflexie, mişcarea putând fi efectuată cu uşurință şi chiar fără a fi nevoie să facă uz de poziții protective ale coloanei lombare în dinamica mişcării, cum ar fi flexarea genunchilor înainte de orice inițiere a mişcării înspre anteroflexie din coloana lombară. Poziția coloanei lombare în decubit dorsal pe masa de tratament putea fi redresată din flexia laterală stânga fără nici o durere, însă odată cu încercarea revenirii la ortostatism pacientul acuza algii în partea dreaptă, coloana ajungând într-o poziție deficitară de flexie laterală stângă, moment în care pacientul nu mai acuza dureri. La măsurarea unghiului de flexie cu goniometrul liniar pacientul avea 25º flexie lateral stânga (fig. 1), făcând posibilă deplasarea doar cu un baston de sprijin.

Fig. 1. Goniometria lombară

Pentru redresarea atitudinii vicioase de flexie laterală stângă, ce ducea şi mai mult la solicitări ale structurilor discale în partea dreaptă, datorită migrării nucleului pulpos spre partea cu presiune redusă (cu creşterea stresului mecanic asupra discului ceea ce producea o agravare a durerilor), s-a recurs la tehnici de mobilizări specifice ale coloanei lombare şi la exerciţii de conştientizare şi redresare activă a poziţiei vicioase (3).

Mobilizările specifice au fost următoarele: a) tehnica rotaţiei lombare după Niederhoffer, cu şi fără facilitare musculară (4) (fig. 2); b) tehnicile mobilizării cu tracţiune bilaterală şi unilaterală după Sohier (5) (fig. 3); c*) hold-relax* cu întindere pe ischio-gambieri (*P.N.F. stretching technique*) (6); d) exerciţiu activ de redresare după conceptul McKenzie (3) (fig. 4).

După 15 şedinţe de efectuare a tehnicilor de mobilizare specifică coloana lombară s-a redresat la 5º de flexie laterală stângă, amplitudinile câştigate făcând posibilă mobilizarea în ambele direcţii de latero-flexie, pacientul acuzând doar o mică jenă în momentul redresării coloanei spre ortostatism.

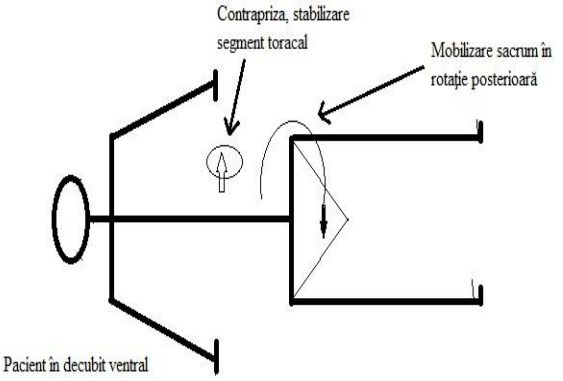

Fig. 2. Mobilizare Niederhoffer

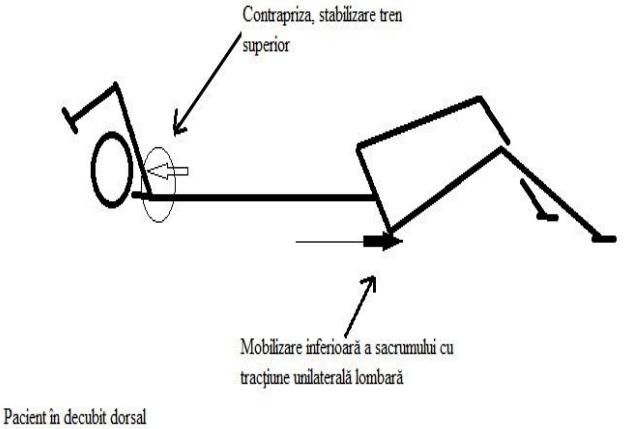

Fig. 3. Mobilizare concept Sohier

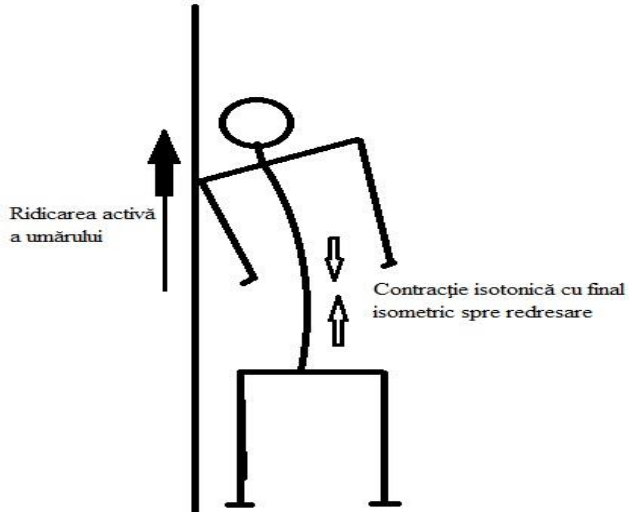

Fig. 4. Redresare activă McKenzie

CONCLUZII .

Studiul nostru a evidenţiat că eşecul restabilirii echilibrului biomecanic la nivelul complexului vertebră-disc-articulaţii interapofizare, deformările şi presiunile inegale păstrate datorită unui restant funcţional de flexie laterală pot duce în timp chiar ele la provocarea de algii importante care să nu mai fie legate de lezarea discală ce a iniţiat dezechilibrul articular.

Mobilizările analitice specifice coloanei lombare rearmonizează complexul articular crescând amplitudinile articulare şi per ansamblu funcţionalitatea.

PREVALENCE OF OBSTRUCTIVE SLEEP APNEA SYMPTOMS IN A RURAL POPULATION (Abstract): **Aim:** Obstructive Sleep Apnea Syndrome (OSAS) is an under diagnosed condition with significant consequences on health. The aim of this study is to estimate the prevalence of symptoms and key features of OSAS in a rural population. **Material and methods:** 254 subjects were enrolled. We measured height (H) and weight (W), calculated body mass index (BMI) and determined glycated hemoglobin (HbA1c). Information about age, gender, medical history (diabetes, hypertension) was collected. All the participants filled in the Berlin questionnaire, which has separate questions regarding the symptoms of OSAS. **Results:** Snoring was reported by 44.1% of the subjects, observed apneas by 6.7% and excessive daytime sleepiness by 36.6%. All symptoms were more frequently reported by women. A higher percentage of obese, hypertensive and diabetics reported snoring ($p<0.001$). When analyzing gender differences, the significance was maintained, except for diabetic men. Witnessed apneas were more prevalent in hypertensive subjects ($p=0.034$), but were significantly associated with hypertension only in ($p=0.003$). No correlation was found regarding excessive daytime sleepiness and the risk factors studied. **Conclusions:** Prevalence of OSAS symptoms and risk factors in this rural population was noticeable and efforts for early diagnosis and treatment are recommended. **Key words:** OBSTRUCTIVE SLEEP APNEA, SLEEP RELATED SYMPTOMS, PREVALENCE.

Sindromul de apnee obstructivă în somn (SAOS) este definit clinic prin apariția repetată a unor episoade de obstrucție completă sau parțială a căilor aeriene superioare în timpul somnului, asociată cu sforăit puternic şi somnolență diurnă (1). Toate aceste trei caracteristici reprezintă simptomele cardinale de apnee.

Acest sindrom are consecințe medicale multiple, cu un impact major asupra sănătății populației. Există o multitudine de evidențe care atestă legătura dintre SAOS şi procesele aterosclerotice (2) sau morbiditatea cardiovasculară (3), în special hipertensiunea arterială (HTA) (4), fiind demonstrată însă şi asocierea acestui sindrom cu insuficiența cardiacă (5), aritmii (6), infarct miocardic (7), accident vascular cerebral (8). Mai mult decât atât, SAOS se asociază cu obezitatea (9) şi tulburări ale metabolismului glucidic (10). De asemenea, simptomele de SAOS se corelează puternic cu

alterarea calității vieții (11), precum şi cu scăderea capacității de muncă (12). Există date care indică faptul că aproximativ 80% dintre pacienții cu SAOS rămân nediagnosticați şi că numai 10% din populație este supusă unui screening adecvat pentru acest diagnostic (13). Recunoaşterea simptomelor şi semnelor de apnee reprezintă primul pas în managementul eficace al acestui sindrom, mai ales la nivelul medicinii primare, unde pacienții cu HTA, obezitate, diabet zaharat (DZ) sau acuze simple precum oboseala sunt foarte frecvent întâlniți. Scopul acestui studiu este de a identifica frecvența simptomelor cardinale de apnee raportate de participanți şi de a evidenția relația acestora cu anumiți factori de risc pentru SAOS (obezitatea, HTA şi tulburările metabolismului glucidic).

MATERIAL ŞI METODE

Am efectuat un studiu transversal pe un lot format din 254 de femei şi bărbați, cu vârste peste 18 ani, aleşi aleator de către computer din 3248 de persoane aflate în bazele de date ale medicilor de familie, alcătuite cu ocazia Programului Național de Sănătate din 2007-2008. Studiul a avut loc la Deleni, cea mai mare comunitate rurală din județul Iaşi. Înainte de începerea studiului s-a obținut avizul Comisiei de Etică a Universității de Medicină şi Farmacie "Grigore T.Popa" Iaşi, fiecare participant completând un formular de consimțământ informat înainte de înrolare.

Datele pentru studiu au inclus vârstă, sex, istoric medical (HTA, DZ). S-au efectuat măsurători antropometrice: greutate, înălțime, utilizând echipamente standardizate. S-a calculat indicele de masă corporală (IMC) prin formula greutate/înălțime^2 (kg/m^2) şi s-au definit categoriile de status ponderal utilizând criteriile OMS: subponderal (IMC< 18,5 kg/m^2), normoponderal (IMC=18,5-24,99 kg/m^2), supraponderal (IMC=25-29,99 kg/m^2) şi obezitate (IMC≥30 kg/m^2). S-a determinat hemoglobina glicată (HbA1c) din sânge capilar. Valoarea HbA1c considerată normală a fost <5.7%. Între 5,7-6,5% s-a stabilit diagnosticul de prediabet, iar o valoare ≥6.5% a diagnosticat DZ. În cadrul aceleiaşi vizite s-a măsurat tensiunea arterială, cu un tensiometru aneroid, şi a fost completat chestionarul Berlin, un instrument folosit pentru evaluarea riscului pentru SAOS (14). Chestionarul include 10 itemi organizați în 3 categorii. Prima categorie se referă la sforăit şi apneele cu martori (întrebările de la 1 la 5), a doua categorie face referire la somnolența diurnă (4 întrebări), iar cea din urmă categorie conține 2 itemi care evaluează existența HTA şi a unui IMC peste 30 kg/m^2. Din analiza separată a întrebărilor conținute în chestionar, s-a evaluat prevalența simptomelor cardinale ale SAOS. Pentru analiza statistică s-a utilizat programul *SPSS* (Statistical Package for Social Sciences) versiunea 16 pentru *Windows*. Semnificația statistică a diferențelor dintre variabilele continui a fost evaluată prin testul *t-Student* şi ANOVA One-way, iar pentru variabilele categoriale s-a utilizat testul χ pătrat (χ^2). O valoare a lui $p<0,05$ a fost considerată ca semnificativă statistic.

REZULTATE

Lotul studiat a fost format din 152 femei (59,84%) şi 102 bărbați (40,15%). Vârsta medie a populației din studiu a fost 55±16,28 ani şi IMC mediu 27,55±5,29 kg/m^2. Din punct de vedere al IMC, 34,5% au fost normoponderali, 36.5% supraponderali şi 29% obezi. În ceea ce priveşte vârsta, majoritatea subiecților s-au încadrat în grupul de vârstă 40-65 ani (47,2%).

Proporția fumătorilor a fost de 21,7%. Hipertensiunea arterială a fost prezentă la 35% dintre participanții la studiu, iar 6,7% aveau diagnostic anterior de DZ; IMC mediu a fost similar la femei şi bărbați. A rezultat că 40,2% dintre subiecți aveau HbA1c normală, 50,4% aveau prediabet şi 9,4% au avut DZ.

Prevalența simptomelor de SAO în lotul studiat a fost de 44,1% pentru sforăit, 6,7% în cazul apneei cu martori şi 36,6% pentru somnolența diurnă. Toate cele trei simptome analizate au fost mai frecvente la femei comparativ cu bărbații (58,9% *vs*. 41.1% pentru sforăit, 88,25 *vs.* 11,8% pentru apneea cu martori şi 66.7% *vs.* 33.3% pentru somnolența diurnă). La 34,3% dintre subiecți s-a găsit prezența atât a sforăitului, cât şi a pauzelor respiratorii în timpul somnului. Dintre sforăitori, 17,9% sunt normoponderali, 34,8% sunt supraponderali, iar 47,3% sunt obezi (p<0,001). Semnificația statistică s-a păstrat şi la analiza separată pe sexe (p<0,001) (tab. I).

TABELUL I

Relația dintre sforăit şi IMC în lotul studiat

Sforăit	Sex	IMC			*p*
		NP (%)	SP (%)	OB (%)	
Da	Bărbați	17,4	34,8	47,8	<0,001
	Femei	18,2	34,8	47,0	<0,001
	Total	17,9	34,8	47,3	<0,001
Nu	Bărbați	46,4	44,6	18,5	<0,001
	Femei	48,8	33,3	17,9	<0,001
	Total	47,9	37,9	14,3	<0,001

Nu au fost relevate diferențe semnificative în ceea ce priveşte apneea cu martori la categoriile statusului ponderal, deşi s-a observat o tendință mai mare a obezilor de a avea pauze respiratorii (12,3%), comparativ cu supraponderalii (5,4%) şi normoponderalii (3,4%) (p=0,068). Această tendință se menține numai în cazul femeilor, dar fără semnificație statistică (p=0,125). Somnolența diurnă a fost identificată la 43,7% dintre normoponderali, 31,5% dintre supraponderali şi 34,3% dintre obezi, fără semnificație statistică (p=0,280).

TABELUL II

Relația dintre HTA şi sforăit în lotul studiat

HTA	Sex	Sforăit (%)		*p*
		Da	Nu	
Da	Bărbați	63,0	37,0	0,026
	Femei	59,7	40,3	0,001
	Total	60,7	39,3	<0,001
Nu	Bărbați	38,7	61,3	0,026
	Femei	32,2	67,8	0,001
	Total	35,2	64,8	<0,001

În ceea ce priveşte relația dintre prezența HTA şi sforăit, rezultatele au arătat că 60,7% dintre hipertensivi sforăie (p<0,001). La bărbați, 63,0% dintre hipertensivi prezintă sforăit, comparativ cu normotensivii (p=0,026). În cazul femeilor, sforăitul s-a întâlnit la semnificativ mai multe femei hipertensive față de cele cu tensiune arterială normală (59,7% *vs.* 32,2%, p=0,001) (tab. II).

Apneea cu martori a fost identificată la 58,8% dintre hipertensivi (p=0,034). HTA a fost găsită la 66,7% dintre femeile la care s-a identificat apneea cu martori, comparativ cu 38% dintre femeile care nu prezentau acest simptom (p=0,003). La nici un bărbat cu HTA nu s-a relevat prezența pauzelor respiratorii în timpul somnului (tab. III). Somnolența diurnă a fost prezentă la 42,7% dintre hipertensivi, comparativ cu 33,3% din normotensivi, fără semnificație statistică (p=0,090). Nu s-au evidențiat diferențe semnificative

între sexe, deşi s-a observat că un procent mai mare de femei cu HTA au somnolență diurnă față de cele fără HTA (48,4% *vs.* 35,6%, p=0,079).

TABELUL III

Relația dintre apneea cu martori şi HTA în lotul studiat

Apnee cu martori	Sex	HTA (%)		*p*
		Da	Nu	
Da	Bărbați	0	100	0,539
	Femei	66,7	33,3	0,003
	Total	58,8	41,2	0,034
Nu	Bărbați	27	73	0,539
	Femei	38	62	0,003
	Total	33,3	66,7	0,034

În ceea ce priveşte HbA1c, 62,5% dintre sforăitori au avut DZ, 49,2% au avut prediabet şi respectiv 33,3% au avut valori normale (p=0,009). Semnificația statistică s-a păstrat doar cazul femeilor, deşi s-a evidențiat şi în cazul bărbaților că un procent mai mare de diabetici sforăie (tab. IV). HbA1c nu s-a corelat cu prezența pauzelor respiratorii în timpul somnului. Mai multe dintre femeile cu DZ au acest simptom față de cele cu prediabet sau cu metabolism glucidic normal, dar nesemnificativ statistic. La nici un bărbat cu DZ nu a fost identificat acest simptom.

TABELUL IV

Relația dintre sforăit şi HbA1c în lotul studiat

Sforăit	Sex	HbA1c			*p*
		Normal (%)	Prediabet (%)	Diabet (%)	
Da	Bărbați	40,0	46,9	62,5	0,468
	Femei	28,1	50,6	62,5	0,009
	Total	33,3	49,2	62,5	0,009
Nu	Bărbați	60,0	53,1	37,5	0,468
	Femei	71,9	49,4	37,5	0,009
	Total	66,7	50,8	37,5	0,009

Cât privește relația dintre somnolența diurnă şi HbA1c, nu s-au găsit diferențe semnificative între grupuri, deşi procentual mai mulți diabetici au somnolență față de prediabetici sau cei cu echilibru glicemic normal (45,8% *vs.* 33,6%, respectiv 38,2%). Prevalența somnolenței la femeile diabetice a fost de 5 ori mai mare față de bărbații diabetici (62,5% *vs.* 12,5%).

DISCUȚII

Apneea obstructivă în somn este un sindrom frecvent subdiagnosticat (13) atât în populația generală, cât şi în grupuri aflate la risc crescut, cum ar fi obezii, hipertensivii sau diabeticii. Se impune detecția precoce a persoanelor care suferă de această boală pentru că astfel s-ar putea preveni apariția unor boli sau îmbunătăți prognosticul acestora, mai ales că există un tratament cu be-

neficii substanțiale pentru aceşti pacienți.

În lipsa tratamentului adecvat, SAOS reprezintă o cauză de mortalitate crescută, existând studii care au investigat influența simptomelor de SAOS asupra mortalității (15, 16). Prevalența simptomelor şi semnelor SAOS variază în funcție de regiunea şi populația studiată (17-19).

În studiul nostru prevalența simptomelor de SAOS a fost de 44,1% pentru sforăit, 6,7% în cazul apneei cu martori şi 36,6% pentru somnolența diurnă. Netzer et al. (17) a găsit rezultate asemănatoare într-un studiu pe 6.223 pacienți ai medicilor generalişti, în Statele Unite ale Americii şi Europa. Sforăitul frecvent şi pauzele în respirație au fost egal raportate (44%) în cele două continente, diferența statistică fiind dată de somnolență (32,4% *vs.* 11,8%), obezitate şi/sau HTA (44,8% *vs.* 37,1%). În cadrul aceluiaşi studiu, s-a găsit că probabilitatea de avea risc înalt de apnee a fost de 5 ori mai mare (OR 5.60; IC 95%, 4,68-6,71) printre persoanele care au raportat istoric de HTA. Când rezultatele au fost ajustate pentru vârstă şi obezitate, corelația pozitivă s-a menținut între HTA şi sforăit. În ceea ce priveşte somnolența diurnă, femeile au raportat-o ca fiind de două ori mai mare față de bărbați. În studiul nostru, rezultatele au fost similare (66,7% *vs.* 33,3%).

Rezultatele studiului efectuat de Bousculet et al. (19) arată o prevalență mai mare a sforăitului (60,2%) şi a apneelor observate (12,3%), dar în cazul somnolenței diurne s-a înregistrat un procent mai mic (16,4%). Un alt studiu pe o populație americană a relevat că 59% din subiecți sforăie, 6% prezintă pauze respiratorii în timpul somnului, iar 26 % au raportat simptome legate de somnolență (18).

Rezultatele noastre au arătat că toate cele trei simptome analizate au fost mai frecvente la femei comparativ cu bărbații, spre deosebire de alte studii care au găsit la bărbați prevalențe mai mari ale sforăitului şi somnolenței (19), sforăitului şi apneei cu martori (17) sau doar a pauzelor respiratorii în timpul somnului (18). Fitzpatrick et al. (20) a raportat o rată a prevalenței net mai mare la bărbați (16%) față de femei (7%). Un studiu recent a identificat o frecvență mai mare a sforăitului la femei (21). În acelaşi studiu, persoanele considerate la risc au avut istoric de DZ (15,3%).

Martikainen et al. (22), într-un studiu pe 5 ani, a găsit că prevalența simptomelor posibil indicatoare ale prezenței apneei în somn (combinația de sforăit şi pauze respiratorii în timpul somnului) s-a ridicat la 4,7% în 1985 şi 7% în 1990. În lotul studiat de noi, prevalența asocierii dintre sforăit şi apneea cu martori a fost de 34,3%.

Bixler et al. (4) a arătat că 37,0% dintre bărbații şi 36,2% dintre femeile care sforăiau aveau HTA, demonstrând o asociere independentă între sforăit şi această afecțiune. Şi în lotul nostru, prezența HTA s-a corelat semnificativ cu sforăitul, atât la femei, cât şi la bărbați. Sivertsen et al. (12) a arătat că persoanele ce aveau simptome de SAOS au prezentat valori semnificative statistic mai mari ale tensiunii arteriale sistolice şi semnificativ mai mulți indivizi aveau DZ. În studiul nostru 62,5% dintre sforăitori aveau DZ.

CONCLUZII

Rezultatele noastre au arătat o prevalență mare a simptomelor precum şi a unor factori de risc pentru SAOS în populația studiată. Toate simptomele analizate au fost mai frecvent raportate de către femei.

Hipertensiunea arterială, obezitatea şi diabetul zaharat s-au asociat semnificativ statistic cu prezența sforăitului, atât la bărbați, cât şi la femei. Apneea cu martori s-a corelat cu HTA, dar numai în cazul femeilor hipertensive a fost identificat mai frecvent acest simptom.

PANCREATIC INVOLVEMENT IN PEDIATRIC HEMATO-ONCOLOGY DISEASES (Abstract): Pancreatic tumors in children and adolescents are rare and represent a different spectrum of cancers in pediatric age. Pancreatic involvement in pediatric hematology and oncology can occur in primary malignant pancreatic tumors or secondary to chemotherapy regimens. Early diagnosis and complete surgical resection of most pancreatic malignancies is associated with long-term survival. Also, childhood cancer treatment increases significant the risk of pancreatic involvement. **Keywords:** PANCREATIC, PEDIATRIC, ONCOLOGY.

Primary malignant pancreatic neoplasms are exceedingly rare in pediatric age and have a better outcome than the adult pancreatic tumors. There is a paucity of data on malignant pancreatic neoplasms in children and the literature consists predominately of single institution case series spread on long periods of time (1). An incidence of all tumors is 0.18 case per million people of malignant pancreatic tumors in 0-19 age group was reported in United States (2). According to the World Health Organization pediatric tumors of the pancreas are classified into exocrine (pancreatoblastomas, solid pseudopapillary tumor, pancreatic adenocarcinoma) and gastroenteropancreatic neuroendocrine tumors.

Pancreatoblastomas (PB) are considered of embryonic origin, as the result of the persistence of pluripotent pancreatic stem cells after the 8 weeks of gestation. PB are very rare neoplasms that usually present in early years of life, most common in children aged 1 to 8-year-old, with a mean age of 4 years (1, 3).

The incidence is 0.004 cases per 100.000 population of all ages per year (4). Over a thirty-year period, ten cases of pancreatoblastoma were recorded in North American population-based Surveillance, Epidemiology and End Results (SEER) (5) and eleven cases in United Kingdom National Registry of Childhood Tumors (6). European cooperative study group for pediatric rare tumors (*EXPeRT* group) collected 20 cases of pancreatoblastomas between 2000 and 2009 (7).

Typically, these tumors are well encapsulated, with a nodular surface. Microscopic appearance consists in characteristic squamous nest (8).

Symptoms include weight loss, upper

abdominal pain, abdominal mass, diarrhea. Because these tumors are asymptomatic most of the time, they may be quite large at the time of the diagnosis. Elevation of serum alpha fetoprotein may occur in most of the cases, but there are no specific markers for pancreatoblastomas.

PB can behave aggressively, distant metastases are usually present at the time of diagnosis and are in liver, lungs, lymph nodes. Also, the invasion into the vessels or nerves may occur. Because of its rarity, standardized diagnostic and therapeutic guidelines are not available yet. The tumor management depends of tumor localization, size and the presence of metastasis. Main stray of therapy is surgical resection, even in high stages PB. PLADO (cisplatin and doxorubicin) regimen is effective for patients diagnosed with PB. Also, other chemotherapy regimens including etoposide, ifosfamide, vincristine, bleomycin can be used. In patients with resected pancreatoblastomas the 5-year survival rate is between 43% - 80% (7, 9).

Solid pseudopapillary tumor (SPT), also known as papillary cystic tumor, is a rare pancreatic neoplasm with a low potential for malignancy. SPT behaves indolently compared to other malignant pancreatic tumors. SPT accounts for 1%-3% of solid pancreatic malignancies and 22% of SPTs occurs in children, mainly in adolescent females, with a male-female ratio of 1:6.5 (10, 11).

Although SPT are solid tumors, they present cystic degeneration secondary to the loss of cellular cohesion (fig. 1). The pseudopapillary pattern is determinate by the relatively preserved cellular cohesion around the microvasculature (fig. 2). Also, aggregates of foamy macrophages, extensive fibrosis, hemorrhage, calcifications may be seen. Immunohistochemical - chromogranin is negative (12).

Fig. 1. Solid pseudopapillary tumor.

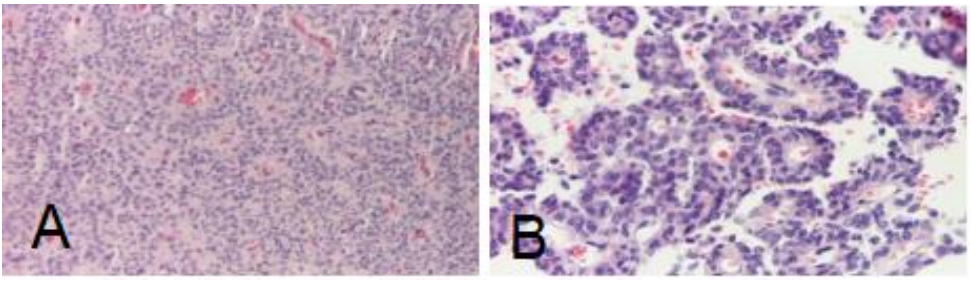

Fig. 2. Solid pseudopapillary tumor – islands of viable tumor with pseudo-papillary, rosette-like architecture (x100 HE) (A); Pseudopapillary pattern (x200 HE) (B).

Clinical findings are nonspecific: palpable abdominal mass, abdominal pain, pancreatitis or dyspepsia. Laboratory tests results, pancreatic exocrine and endocrine

function are preserved. There is no preoperative serum tumor marker predictive for solid pseudopapillary tumor (13). On ultrasound, SPTs appear as encapsulated, well demarcated masses, with solid and cystic components. Computed tomography and magnetic resonance imaging are needed for staging (14). The metastatic lesions are uncommon, in a small percentage of patients are present in the liver, omentum and peritoneum at the time of diagnosis (1). Depending on location, the suitable treatment with excellent results for solid pseudopapillary tumor is complete surgery. Local invasion limited metastatic lesions or recurrence do not contraindicate surgical resection (10). Chemo-radiotherapy and oral retinoid therapy were successfully used in patients with SPT, but their role in SPT treatment is not defined (15, 16). Adjuvant therapy is indicated when surgical approach is inappropriate (16). SPTs are usually resectable and associated with excellent prognosis. Several studies have shown high cure rate, around 95% of patients, that underwent complete surgical excision (17).

Pancreatic adenocarcinomas, ductal adenocarcinoma and acinar cell carcinoma, are the less common pancreatic pediatric tumors, with a poor prognosis.

Ductal adenocarcinoma it is exceptionally found in children, it has been reported in teenaged patients. It common affects the head of the pancreas (18).

Presenting symptoms are obstructive jaundice, abdominal pain, weight loss (19). Ultrasound of the abdomen often show a small hypo vascular mass, with inconstant dilatation of the pancreatic duct due to the tumoral mass. Ductal adenocarcinoma has a similar prognosis for children and adults (20, 21).

Imagistic studies of acinar cell carcinoma describe well circumscribed mass, with area of necrosis. Metastatic lesions are common at the diagnosis. The prognosis seems to be favorable in children than in adults (22).

Pancreatic islet cell tumors are endocrine tumors seen in infants and children. They can be classified as functioning (insulinomas, gastrinomas, ACTHomas, VIPomas) or nonfunctioning.

Gastrinomas are more frequently malignant tumors. The diagnosis is based on hypergastrinemia and gastric hypersecretion. Because of their extra pancreatic localization, indium octreotide scintigraphy is used (23). Surgical resection is indicated in all cases. Chemotherapy has been used in several cases of metastatic gastrinomas.

Insulinomas are quite rare among children, 4 cases per million individuals per year and only ten percent of them are malignant. Insulinomas are functional insulin secreting neuroendocrine tumors. The hypoglycemia induced symptoms consist in dizziness, sweating, headaches and Whipple's triad is described in these patients (24, 25) (fig. 3).

The biological investigations of insulinomas includes glucose levels quickly dropping, increased C-peptide levels and high levels of circulating insulin and proinsulin.

Surgical resection is recommended in all patients diagnosed with insulinoma. Chemo-radiotherapy, chemo-embolization, biotherapy is also indicated in malignant forms of insulinomas (26). In adult population, in addition to chemo-radiotherapy, there seems to be positive effects associated to several natural polyphenols used to induce apoptosis in some types of cancer (27). Nonfunctioning pancreatic endocrine tumors have no specific symptoms and delay the diagnosis. Often, patients present with abdominal pain secondary to local invasion or metastases (28).

Chemotherapy drugs used in the treatment of many pediatric solid tumors and hematological malignancies can induce severe pancreatic complications which may discontinue the chemotherapy regimens and prolong hospitalization.

Acute pancreatitis (AP) is known as a possible complication of high-risk chemotherapy regimen. A variate number of chemotherapeutics such as L-asparaginase, Mercaptopurine, Cytosine arabinoside, ifosfamide, cisplatin, doxorubicin is considered implicated in chemotherapy induced acute pancreatitis (29).

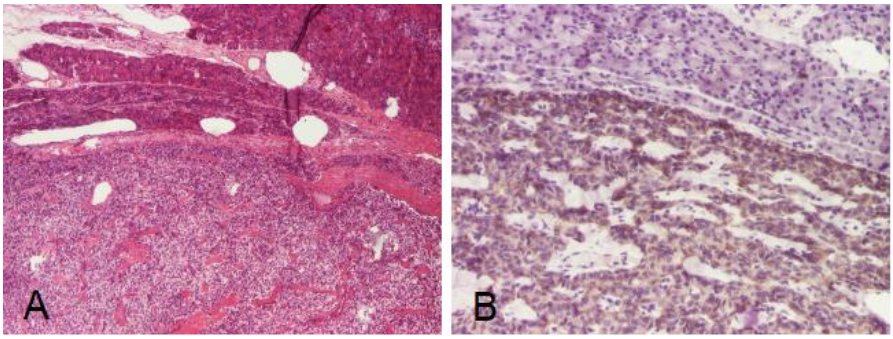

Fig. 3. Pancreatic insulinoma: solid pattern of pancreatic insulinoma (x40 HE stains) (A); Immunohistochemistry positive for chromogranin A (x100) (B).

CONCLUSIONS

Pancreatic involvement in pediatric hematology and oncology can occur in primary malignant pancreatic tumors or secondary to chemotherapy regimens used in childhood cancers. Prognosis of pediatric patients with malignant pancreatic tumors is variable and depends of histologic type. Also, monitoring of pancreatic toxicity and initialization of treatment as early as possible is recommended in children who undergo chemotherapy.

ISSUES ON THE USE OF ETHNOBOTANICALS (Abstract). **Aim**: To identify the risk factors for the use of ethnobotanicals and the people at risk to becoming users. **Material and methods**: This questionnaire basez objective population study included 89 subjects aged 14 to 42 years. **Results**: 19.10% of the subjects admitted using ethnobotanicals, most of them being 20-25 years old (35.29%), males (82.35%), with an average educational level, and unmarried. It should be noted that 23.52% of the users were underage. 85.15% of the subjects first used ehnobotanicals out of curiosity, 29,41% under the influence of friends (94.11% of them having friends that use these products). 11.76% of the respondents stated that they did not know what they used, the product being offered to them by friends as a cigarette or candy. Favorite places for consumption were: at home (64.70%), parks and public areas (23.52%), coffee shops and night clubs (11.76%). Cigarette was the preferred method of use (70.58%), followed by joint (23.52%) and "salt bath" (5.88%). The described effects were: hallucinogen (35.29%), aphrodisiac (29.41%) and relaxing (23.52%). To strengthen these effects, most users associated alcohol and tabacco (70.58%), or other illegal drugs (7.14%). According to this study all users were familiar with the risks associated with the use of these products, but only 64.70% agree with closing the weed-shops. **Conclusions**: The obtained data are of help in initiating prevention and rehabilitation programs in school and colleges. **Key words**: ETHNOBOTANICAL PRODUCTS, DRUGS, CONSUMPTION, RISK FACTORS.

România se situează pe locul IV în lume la consumul de plante etnobotanice, după Anglia, Germania şi Olanda (1,2,3).

Prezenta lucrare este o secțiune dintr-un studiu mai amplu efectuat la Spitalul Clinic Județean de Urgențe „Sf. Spiridon" Iaşi, şi are drept scop identificarea principalilor factori de risc care duc la consumul de produse etnobotanice.

MATERIAL ŞI METODE

S-a întreprins o anchetă populațională, realizată pe data de 25 iunie 2011, cu ocazia Zilei Mondiale Antidrog, în oraşul Iaşi, în diferite puncte cu caracter informațional. Lotul inclus in studiu a cuprins 89 subiecți cu vârsta între 14 şi 42 ani, evaluati pe bază de chestionar (19 itemi) care a vizat înregistrarea feedback-ului subiectiv cu privire la produsele etnobotanice şi implicit la consumul acestora, iar rezultatele au fost analizate statistic. Cercetarea clinică a permis evaluarea percepției subiective a participanților referitor la consumul de produse etnobotanice, starea psihică, relații sociale şi starea generală de sănătate. Prelucrarea

statistică s-a realizat prin crearea unei baze de date computerizată cu ajutorul programului *SPSS 18.0*, ulterior realizându-se interpretarea rezultatelor.

REZULTATE ŞI DISCUŢII

În urma prelucrării datelor reiese că, majoritatea persoanelor din lotul de studiu se încadrează în categoria de vârstă 20-25 (47,19%), 18-20 ani (25,84%) şi minori (13,48%), iar distribuţia pe sex arată o repartiţie relativ egală a subiecţilor (44,94% femei şi respectiv 55,06% bărbaţi) (fig.1, 2).

Nivelul educaţional situează majoritatea persoanelor cu studii în curs de desfăşurare (58,42%), studii liceale (17,97%) şi universitare (20,22%).

Din totalul persoanelor chestionate, 19,10% au recunoscut că au consumat produse etnobotanice, ponderea cea mai mare revenind sexului masculin (82,35%). De remarcat este faptul că, 23,52% dintre consumatori sunt minori, un procent mai mare revenind categoriei de vârstă 20-25 ani (35,29%) (fig. 3).

Majoritatea consumatorilor evaluaţi prin ancheta populaţională sunt necăsătoriţi (82,35%) şi doar 11,76% au studii universitare (studii gimnaziale 5,88%, studii liceale 58,82%, studii postliceale 23,52%) (fig. 4).

Dintre consumatori, 64,70% au achiziţionat produsele de la „*weed-shop*”, 5,88% de la dealeri, 29,41% fiindu-le oferite de prieteni. Consumul produselor etnobotanice din curiozitate a fost semnalat la 82,35%, influenţa prietenilor fiind responsabilă de 23,52% din cazuri, iar 11,76% au declarat că nu au ştiut ce consumă, produsul fiindule oferit sub formă de bomboane sau ţigări.

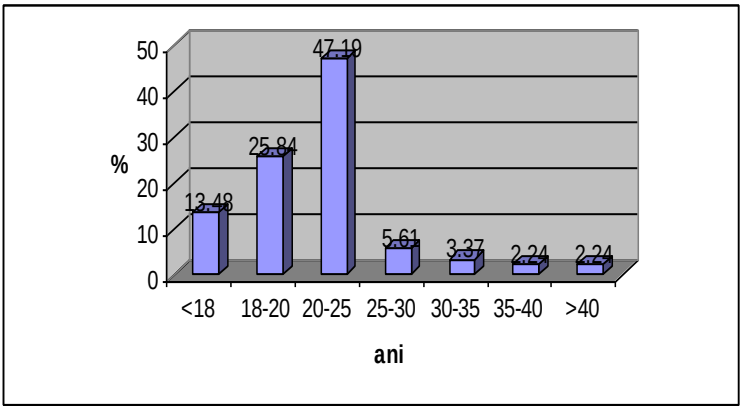

Fig. 1. Distribuţia pe grupuri de vârstă a persoanelor incluse în studiu

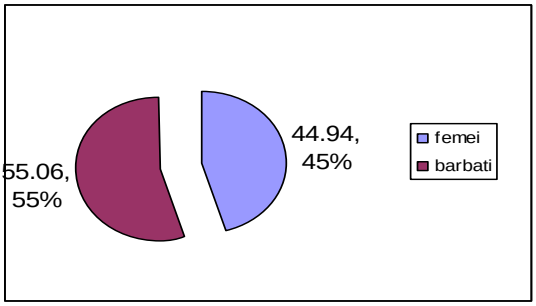

Fig. 2. Distribuţia persoanelor incluse in studiu în relaţie cu sexul

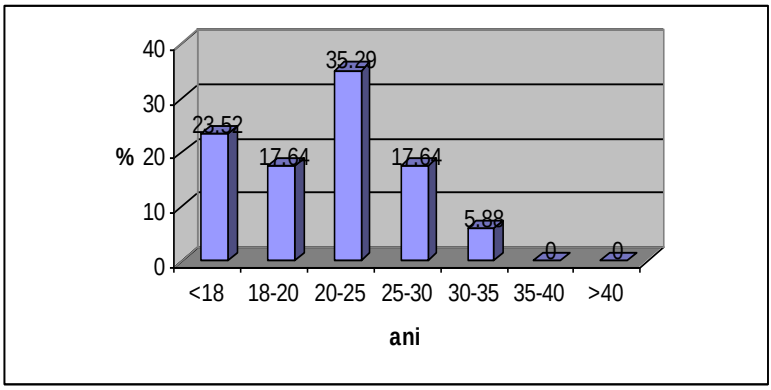

Fig. 3. Distribuția pe grupuri de vârstă a consumatorilor de produse etnobotanice

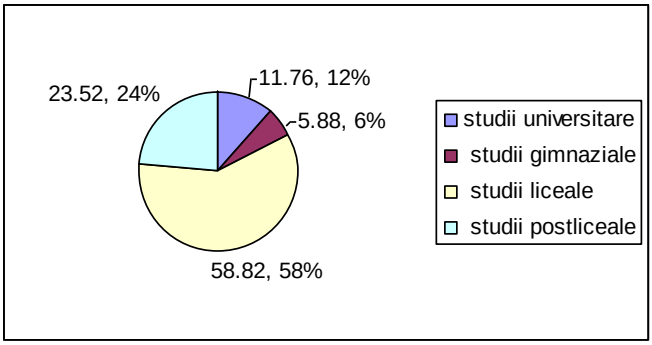

Fig. 4. Distribuția consumatorilor de produse etnobotanice în relație cu nivelul educational

Locurile preferate de consum al acestor produse sunt: locuința proprie (64,70%), parcuri, spații publice (23,52%), cafenele şi cluburi de noapte (11,76%).

Modalitatea preferată de consum este țigara (70,58%), urmată de *joint* (23,52%) şi "sare de baie" (5,88%). Efectul perceput de consumator a fost descris ca fiind halucinogen (35,29%), afrodisiac (29,41%) şi relaxant (23,52%). Pentru potențarea acestor efecte majoritatea consumatorilor asociază produsele etnobotanice cu alcool şi tutun (76,47%), sau cu alte droguri ilegale (11,76%). Cele mai cunoscute şi implicit consumate produse etnobotanice sunt "Pure by Magic" şi "Flower Magic" (68%), ambele produse fiind cunoscute ca îngrăşăminte pentru plante. Modalitatea de consum a acestor produse este administrarea intranazală.

Analiza cromatografică a produsului "Pure by Magic" a dus la identificarea a două pirovalerone: MDPBP [1-(3,4- metilendioxifenil)-2-(pironidil)-1-butanonă] şi MDPV (metilendioxipirovalerona), droguri psihoactive cu proprietăți stimulente (similare cocainei şi amfetaminei) (fig. 5, 6). Aceste substanțe determină creşterea concentrației extracelulare a norepinefrinei şi a dopaminei, implicit creşterea neurotransmițătorilor andrenergici şi dopaminergici, efect responsabil de o serie de manifestări adverse care pot duce la decesul persoanei consumatoare (4,5) .

Începând cu anul 2010, MDPV şi

MDPBP au fost interzise în majoritatea țărilor. În România aceste pirovalerone au fost introduse pe lista de substanțe interzise, proiect de lege care nu a fost încă aprobat.

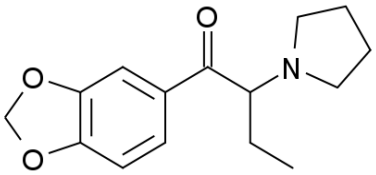

Fig. 5. MDPBP [1-(3,4-metilendioxifenil)-2-(pirodinil-1-butanona]

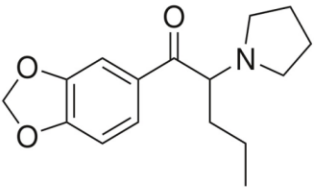

Fig. 6. MDPV (metilendioxipirovalerona)

Studiul a evidențiat faptul ca toți consumatorii cunosc riscurile la care se expun atunci când folosesc aceste produse, însă, doar 64,70% sunt de acord cu închiderea magazinelor care le comercializează .

CONCLUZII

Lotul de studiu a cuprins 89 de respondenți cu vârste între 14-42 ani. Din totalul persoanelor evaluate, 19,10% au recunoscut că au consumat produse etnobotanice, ponderea cea mai mare aparținând grupului de vârstă 20-25 ani (35,29%), fiind de sex masculin (82,35%), cu un nivel educațional mediu şi necăsătorite.

Principalii factori de risc care pot duce la consumul de produse etnobotanice s-au dovedit a fi anturajul şi accesibilitatea la achiziționare a acestor produse.

Rezultatele cercetărilor pot fi utilizate pentru elaborarea unor programe de prevenție şi reabilitare a diferitelor grupuri de vârstă expuse la riscurile consumului de produse etnobotanice.

BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS (Abstract): Patients with rheumatoid arthritis (RA), an immune-mediated inflammatory rheumatic disease with peripheral and systemic involvement, are at increased risk of bone loss and fractures. There are many reasons for the high prevalence of osteoporosis (OP) in RA, including both traditional and specific risk factors such as pain and loss of joint function, medication (corticosteroids, methotrexate), and increased proinflammatory cytokines. **Aim:** To evaluate bone mineral density status in RA patients, focusing on potential relation with classical risk factors for OP. **Material and methods:** One-year prospective observational study on 83 consecutive postmenopausal women, 43 diagnosed with RA (group I), and 40 healthy controls (group II) with no previous condition and medication known to affect bone metabolism and turnover. Bone mineral density (BMD) and T-score evaluated by dual X-ray absorbtiometry (DXA) at three standard skeletal sites (L1-L4 lumbar spine, hip and forearm) (Hologique QDR 100 device), and classical risk factors for osteoporosis were assessed in all patients according to a predefined protocol. Data were analyzed in SPSS-13 using ANOVA, t-Student, chi-square and ROC (Receiver Operator Characteristic). **Results:** Decreased BMD was reported in the majority of RA cases, mainly in the spine and femoral neck (86%), but also in total hip (72%); moreover, osteoporosis was commonly demonstrated in lumbar spine and osteopenia at hip level. Statistically significant differences between diagnostic categories (normal, osteopenia, osteoporosis, WHO 1994) ($p<0.05$), while no significant differences between mean BMD levels in women with and without RA at different skeletal sites were found (t-student, $p>0.05$). However, considerable BMD variation (51.7% to 102.3%) was suggested in RA as compared to non-RA patients (14.3% to 27%) (ANOVA). Significant differences in mean T-score at total hip and forearm (mainly 33% radius) were noted in patients with and without RA ($p<0.05$). No relation between osteodensitometric parameters and classical risk factors for OP has been identified in RA, except menopause. Indirect weak statistically significant correlations were found between mean T-score and menopause duration at all skeletal levels (Pearson's rank correlation, $p<0.05$), except for the femoral neck ($r=+0.03$, $p<0.05$). **Conclusions:** Decreased BMD is commonly seen in RA patients. Several characteristics based on DXA assessment have been identified, including preference for distinct skeletal sites (spine, hip, distal forearm), and the particular intervention of menopause. **Key words**: BONE MINERAL DENSITY, OSTEOPOROSIS, RHEUMATOID ARTHRITIS, MENOPAUSE

Poliartrita reumatoidă (PR) este o boală dizabilitantă de tip autoimun, cu evoluţie periferică, la nivel articular, şi sistemică (1). Studiile din literatura de specialitate au demonstrat că bolnavii cu PR au risc crescut pentru pierderea de masă osoasă şi fractură de fragilitate (2, 3). În prezent se recunosc multiple mecanisme inductoare ce includ: durerea şi limitarea funcţională, medicaţia (glucocorticoizi, AINS, metotrexat), precum şi inflamaţia ce caracterizează evoluţia bolii (1, 4). Dat fiind faptul că osteoporoza la bolnavul cu PR este o complicaţie redutabilă, generatoare de durere şi fractură, apare necesitatea particularizării ei sub raportul factorilor de risc generaţi de boala de bază, clinici şi terapeutici (5, 6).

Studiul de faţă îşi propune măsurarea comparativă a densităţii minerale osoase (DMO) prin metoda absorbţiometriei duale cu raze X (DXA) la femei în etapa postmenopauzală, cu sau fără diagnosticul de PR, cu scopul evidenţierii unor particularităţi impuse de boala de bază, dar si pentru a evidentia eventualele relaţii particulare cu factorii tradiţionali de risc pentru osteoporoză în cazul pacientelor cu PR, cu semnificaţie pentru practica clinică.

MATERIAL ŞI METODĂ

Am realizat un studiu prospectiv observaţional cu durata de 12 luni asupra unui lot format din 43 paciente consecutive diagnosticate cu poliartrită reumatoidă (criteriile ACR, 1987) (lotul I) spitalizate în Clinica Reumatologie, Spitalul Clinic de Recuperare Iaşi, în perioada 2009-2010, la care s-a urmărit densitatea minerală osoasă (metoda DXA) şi factorii de risc clasici pentru osteoporoză, respectiv aportul de calciu şi vitamina D, excesul de noxe (alcool, cafea, fumat), istoricul familial de fractură de şold, indicele de masă corporală (IMC), menopauza precoce şi corticoterapia cronică (7, 8). Evaluarea osteodensitometrică DXA (aparat Hologic QDR) a fost realizată pe situsuri scheletale multiple, la nivel vertebral (L1-L4), şold (col femural, şold total) şi antebraţ (treimea distală, medie, proximală, antebraţ total), interesându-ne atât T-*score* cât şi densitatea minerală osoasă (DMO, g/cm^2); au fost utilizate valorile prag validate internaţional (OMS, 1994) pentru a defini categoriile diagnostice, şi anume : $\pm$1 deviaţie standard (DS) pentru T-*score* în limite normale, -1 DS < T-*score* <-2.5DS pentru a defini osteopenia şi T-*score*<-2.5 DS pentru osteoporoză. Au fost luate în atenţie doar paciente cu poliartrită reumatoidă aflate în etapa postmenopauză.

Lotul martor (lotul II), comparabil ca număr, vârsta şi sex cu lotul de studiu, a fost alcătuit din 40 femei în postmenopauză nediagnosticate cu patologie reumatismală inflamatorie cronică (poliartrită reumatoidă, lupus, spondilartrite) sau patologie osoasă metabolică. Determinările DXA au respectat şi în acest lot protocolul standard propus pentru lotul I.

Datele au fost analizate şi interpretate statistic în programele EXCEL, EPIINFO, SPSS, interesându-ne testele ANOVA, t-Student, chi-pătrat şi balanţa de sensibilitate/ specificitate - curba ROC (Receiver Operator Characteristic).

REZULTATE

Parametri osteodensitometrici

Repartiţia pe categorii diagnostice la pacientele cu şi fără PR

La pacientele diagnosticate cu PR, analiza frecvenţelor diferitelor catogorii diagnostice raportat la parametrul central de analiză, DXA, a relevat următoarea distri-

buţie pe regiunile scheletale investigate: (i) T-*score* în limite normale - coloană lombară 14%, şold total 27,9%, col femural 14%, (ii) paciente cu osteopenie - coloană lombară 32,6%, şold total 58,1%**,** col femural 53,5%, (iii) paciente cu osteoporoză - coloană lombară 53,5%, şold total 14%**,** col femural – 32,6%. Astfel, în majoritatea cazurilor de PR, reţinem afectarea densităţii minerale osoase indiferent de prezenţa sau nu a factorilor clasici de risc pentru osteoporoză; procente maximale (86%) sunt decelate atât la nivelul segmentului lombar cât şi la nivelul colului femural, în timp ce şoldul total este afectat în procent de 72%. Mai mult, se pare că la pacientele cu PR osteoporoza predomină la nivel vertebral, în timp ce valori ale DMO şi T-*score* în interval de osteopenie sunt reprezentate preferenţial la nivelul şoldului (total, col femural).

Evaluarea DXA la pacientele fără PR a evidenţiat următoarele aspecte: (i) T-*score* în limite normale - şold total 7,5%, (ii) paciente cu osteopenie - coloană lombară 37,5%, şold total 70,0%, col femural 55,0%, (iii) paciente cu osteoporoză - coloană lombară 62,5%, şold total 22,5%, col femural 45,0%.

Studiul comparativ pe cele două loturi selectate a evidenţiat frecvenţa mai mare a afectării DMO la pacientele fără PR; ca şi în lotul de paciente cu PR, predomină însă osteoporoza la nivel vetebral şi osteopenia la nivelul şoldului. Mai mult, am înregistrat diferenţe semnificative statistic între frecvenţele diferitelor categorii diagnostice la paciente cu şi fără PR ($p<0.05$) pe regiunile scheletale investigate. Datele prezentate sunt sumarizate în figura 1 şi în tabelul I.

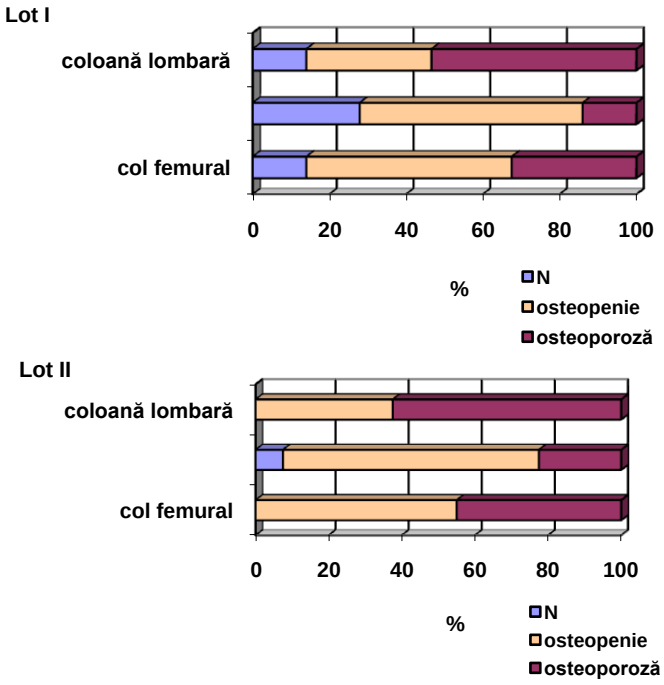

Fig. 1. Distribuţia pacientelor din loturile I şi II în funcţie de clasificarea DXA

TABELUL I

Diferenţe statistice în funcţie de clasa de boală pe loturi de studiu

Clasificarea OMS	Lot I		Lot II		p
	n	%	n	%	
Coloană lombară					
Normal	6	14,0	0	0	**0,042**
Osteopenie	14	32,6	15	37,5	
Osteoporoză	23	53,5	25	62,5	
Şold total					
Normal	12	27,9	3	7,5	**0,033**
Osteopenie	25	58,1	28	70,0	
Osteoporoză	6	14,0	9	22,5	
Col femural					
Normal	6	14,0	0	0	**0,042**
Osteopenie	23	53,5	22	55,0	
Osteoporoză	14	32,6	18	45,0	

Densitatea minerală osoasă la pacientele cu şi fără PR

Valorile medii ale densităţii minerale osoase la toate nivelurile investigate la pacientele cu PR au fost următoarele: coloana lombară (0,780 ± 0,140), şold total (0,780 ± 0,130), col femural (0,680 ± 0,100), antebraţ cu valori diferenţiate pe cele trei regiuni: antebraţ total (0,460 ±0,080), 1/3 radius distal (33% radius) (0,530 ±0,090), treimea medie a antebraţului (0,460 ± 0,090), antebraţ ultradistal (0,360±0,090).

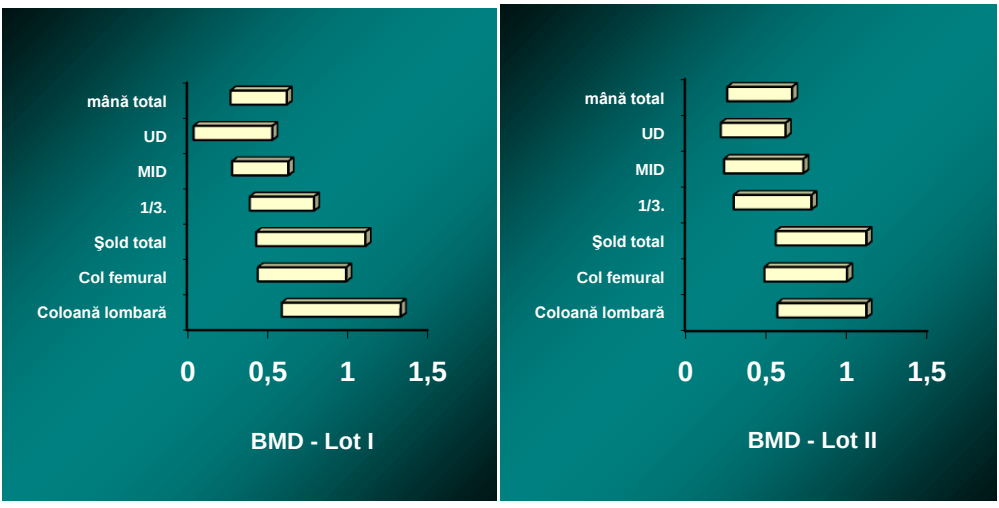

Fig. 2. Seriile de valori ale DMO pe niveluri analizate comparativ pe loturi de studiu

Valorile medii ale densităţii minerale osoase pentru pacientele fără PR au fost următoarele: coloana lombară (0,080± 0,150), şold total (0,790±0,130), col femural (0,700±0,130); pentru antebraţul total valorile înregistrate au fost de 0,480±0,100, pentru regiunea 1/3 radius distal (0,570± 0,130), pentru treimea medie a antebraţului (0,490±0,120), iar pentru antebraţul ultradistal valorile au fost de 0,390±0,100.

Nu s-au înregistrat diferenţe semnificative statistic între valorile medii ale DMO pe diferite regiuni scheletale la pacientele celor două loturi. S-au obţinut astfel următoarele rezultate pentru testul *t-Student*: 1/3 radius distal (1,62), treimea medie a antebraţului (1,28) şi antebraţ ultradistal (1,43).

Cu toate acestea, dacă în lotul de PR se constată variaţii foarte ample ale DMO (de la 51,7% până la 102,3%), pacientele fără PR se definesc prin valori mai omogene ale DMO (14,3% - 27%) (test ANOVA).

T-score la pacientele cu şi fără PR

Valorile individuale medii ale T-*score* pe nivelurile scheletale investigate au fost următoarele, în cazul lotului de PR: coloana lombară (-2,32±1,20), şold total (-1,46±1,29), col femural (-2,13±1,04); pentru regiunea antebraţului avem: antebraţ total (-2,22±1,57), 1/3 radius distal (-2,69±1,55), treimea medie a antebraţului (-2,59±1,58), antebraţ ultradistal (-1,28± 1,31).

Pentru pacientele fără PR au fost raportate următoarele valori medii ale T-*score*: coloana lombară (-2,52±0,41), şold total (-2,04±0,55), col femural (-2,33± 0,52), antebraţ total (-2,59±0,42), 1/3 radius distal (-3,14±0,45), treimea medie a antebraţului (-2,97±0,48), antebraţ ultradistal (-2,87± 0,42). Datele sunt prezentate sintetic în figura 3.

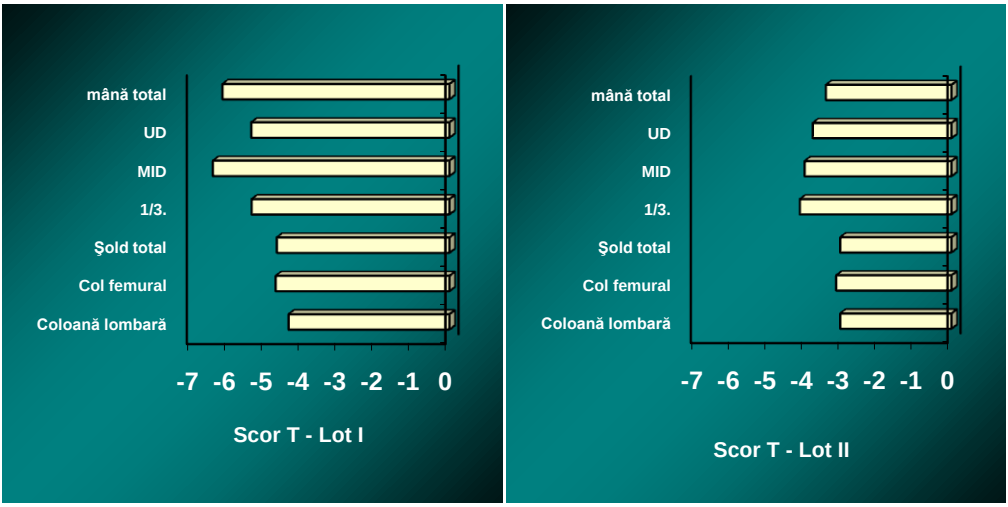

Fig. 3. Seriile de valori ale T-*score* pe niveluri analizate comparativ pe loturi de studiu

Reţinem faptul că valorile medii ale T-*score* confirmă caracteristicile de frecvenţă enunţate anterior pentru ambele loturi, şi anume predominanţa osteoporozei la nivel de coloană lombară şi a osteopeniei la nivelul şoldului (total, col femural).

Am înregistrat diferenţe semnificative statistic între valorile medii ale T-*score* între

cele două loturi de studiu doar la nivelul şoldului total şi la antebraţ, la nivelul antebraţului ultradistal. Datele obţinute sunt următoarele: *t-Student* pentru coloana lombară este de 1,03, pentru şoldul total 2,70, col femural 1,12, antebraţ total 1,49, 1/3 radius distal 1,82, treimea medie a antebraţului 1,50, antebraţ ultradistal 7,55 ($p<0,05$). Celelalte regiuni scheletale nu au înregistrat diferenţe semnificative statistic pentru T-*score* mediu.

În general, valorile medii ale parametrilor osteodensitometrici nu prezintă diferenţe semnificative între cele două loturi de studiu.

Factori clasici de risc pentru osteoporoză

Variaţia seriilor de valori individuale ale subiecţilor din cele două loturi a indicat valori comparabile raportat la aspectele legate de vârstă, greutate, talie şi IMC. Astfel, pentru pacientele cu PR, în ceea ce priveşte valorile medii, acestea au fost de 60,67±7,35 , iar pentru IMC – 26,10±4,18. Pentru pacientele din lotul II valorile sunt, respectiv, de 59,38±4,71, pentru vârstă, şi de 25,50±2,33 pentru IMC.

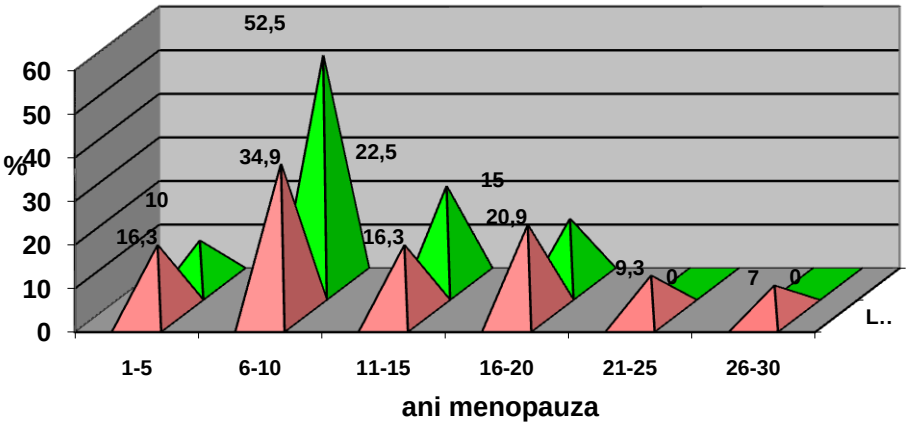

Fig. 4. Distribuţia pacientelor în funcţie de anii de menopauză

Distribuţia în funcţie de anii de menopauză este descrisă în fig. 4, susţinând predominanţa intervalului 5-10 ani postmenopauză în ambele loturi de studiu (35%, respectiv 53%).

Corelaţii între parametrii osteodensitometrici şi factorii de risc clasici pentru osteoporoză

T-score şi durata menopauzei la pacientele cu PR

În general au fost observate doar slabe corelaţii indirecte între *T-score* şi vechimea menopauzei (r Pearson, $p<0,05$); astfel notăm următoarele valori ale parametrului "r", funcţie de sediul scheletal investigat: coloana lombară (r=-0,10), col femural (r=+0,03), şold total (r=-0,13), antebraţ total (r=-0,22), treimea medie a antebraţului (r=-0,26), antebraţ ultradistal (r=-0,20), 1/3 radius distal (r=-0,14). Datele prezentate evidenţiază scăderea T-*score* cu atât mai mult cu cât vechimea menopauzei este mai mare.

Excepţie de la corelaţia între durata menopauzei şi T-*score* se observă la colul

femural (r = +0,03); cele mai puternice asocieri indirecte între T-*score* cu vechimea menopauzei se observă la mână: r = -0,22 la nivelul 1/3 radius distal; r = -0,26 în treimea medie a antebraţului; r = -0,20 la nivelul antebraţului ultradistal.

Nu au fost decelate relaţii cu semnificaţie statistică între parametrii osteodensitometrici şi alţi factori clasici de risc ai OP la pacientele cu PR.

DISCUŢII

Studiul osteodensitometric efectuat oferă o imagine complexă asupra statusului densităţii minerale osoase la paciente cu poliartrită reumatoidă aflate în etapa de postmenopauză. Datele obţinute se înscriu între cele menţionate în literatura de specialitate a ultimilor ani, care precizează faptul că poliartrita reumatoidă se asociază atât cu pierderea localizată (9, 10) cât şi cu cea generalizată (11) de masă osoasă, creşterea riscului de osteoporoză şi fractură de fragilitate (12, 13)**.**

Studiul de faţă precum şi cele prezentate în literatura internaţională demonstrează că măsurarea pierderii de os la pacienţii cu PR prin DXA la nivelul diferitelor segmente (atât central cât şi periferic) este o metodă de diagnostic importantă pentru detectarea osteoporozei (14)**.**

Retinem în studiul de faţă o serie de particularităţi legate în principal de procentul mare de paciente care prezintă scăderea densităţii minerale osoase (osteopenie, osteoporoză) în poliartrita reumatoidă şi situsurile scheletale cele mai afectate (listate în ordinea descrescătoare a frecvenţei, coloană, şold, antebraţ distal). Acest lucru este semnificativ în special pentru pierderea periferică de masă osoasă, care se găseşte în relaţie directă cu variabilele specifice bolii, precum şi factorii de risc cunoscuţi pentru osteoporoză.

Spre deosebire de cele demonstrate în cercetarea noastră, Haugeberg şi colab, 2007 (10) nu au identificat diferenţe în ceea ce priveşte densitatea minerală osoasa la nivel lombar şi şold total; mai mult, au fost evidenţiate valori semnificativ scăzute ale densităţii la nivelul antebraţului prin tehnica DXA. Scăderea DMO la nivelul regiunii distale a antebraţului a fost raportată în PR de Iwamoto şi colab, 2002 (3), în timp ce o scădere semnificativă a DMO la pacienţii cu PR la nivelul tuturor regiunilor scheletale examinate cu excepţia segmentului vertebral, a fost demonstrată şi de Shibuya şi colab., 2002 (15).

Faptul că pacientele cu PR înrolate în studiul nostru au prezentat scăderea DMO în majoritatea cazurilor independent de existenţa factorilor de risc clasic recunoscuţi pentru osteoporoză, sugerează participarea altor factori la afectarea DMO la această categorie de paciente. Intervenţia dezechilibrului citokinic (predominanţa citokinelor proinflamatorii), a activităţii PR, afectarea funcţională cu limitare semnificativă a exerciţiului fizic cotidian precum si medicaţia cu impact asupra metabolismului osos (corticoterapie, metotrexat) sunt factori recunoscuţi în determinismul OP secundare PR (16,17).

CONCLUZII

Poliartrita reumatoidă înregistrează pierderea de masă osoasă ca o complicaţie frecventă care necesită diagnostic şi conduită terapeutică specială. Studiul comparativ al încărcării minerale osoase centrale (coloană, şold, antebraţ) prin metoda DXA pune în valoare o serie de particularităţi legate de boala de bază, care se referă în principal la sediile cele mai afectate precum şi la relaţia cu menopauza.

1. Doctorand al Universității de Medicină şi Farmacie "Gr. T. Popa" Iaşi
2. Spitalul de Pediatrie „Sf. Ioan" Galați, Compartiment Dializă
3. Clinica a IV-a de Nefrologie Pediatrică „Sf. Maria" Iaşi

THERAPEUTIC ASPECTS OF ACUTE RENAL FAILURE IN CHILDREN (ABSTRACT): This article presents the results of a study on 20 children diagnosed with acute renal failure and treated with renal substitution methods at the Iasi IVth Clinic of Pediatric Nephrology în the interval 2003-2008. Treatment by intermittent hemodialysis IHD), peritoneal dialysis (DP), and continuous replacement – hemofiltering (HF) depends on the patient's features and unit resources. The advantages and limitations of every method of treatment are discussed. Future therapies for acute renal failure may find strategies for eliminating the inflammatory response. **Key words:** ACUTE KIDNEY FAILURE, TREATMENT, CHILDREN

Leziunea renală acută are o contribuție semnificativă în morbiditatea şi mortalitatea copiilor în stările critice, în special la cei cu insuficiență organică multiplă.

În ultima decadă s-a schimbat epidemiologia leziunii renale acute, accesul la tratament, obiectivele şi tehnologiile rafinate ale echipamentelor de monitorizare şi de supleere renală (1,2).

Înțelegerea fiziopatologiei insuficienței renale acute, utilizarea biomarkerilor precoce şi o mai bună clasificare, necesită dezvoltarea strategiilor terapeutice de succes pentru leziunea renală acută la copil (3,4,5,13).

a. Prevenirea leziunii renale acute are un larg impact asupra ratei mortalității. Cea mai obişnuită cauză de insuficiență renală în copilărie este depleția volemică şi aceasta poate fi prevenită. Măsurile terapeutice profilactice constau în evitarea deshidratării şi medicamentelor nefrotoxice concomitent, în special la copiii cu afectare renala preexistentă.

Terapia de atenuare a leziunii renale şi de promovare a recuperării

Deşi nu există o terapie specifică pentru prevenirea leziunii renale la om, au început să fie studiate mai multe terapii potențiale (6,7). Managementul leziunii renale acute poate să includa antioxidanți, terapia cu molecule împotriva adeziunii şi administrarea de mediatori vasculari sau celule stem mezenchimale care să prevină leziunea şi să promoveze recuperarea (6,8,10, 12,15).

- Hormonul de stimulare a melanocitelor (MSH) are activitate antiinflamatorie şi s-a dovedit că protejează tubulii renali de leziune (9).

-Pe modele animale cu leziune renală acută, infuzia postischemică de factori de creştere (incluzând insulin-like factor de creştere, factori epidermici de creştere şi factori de creştere hepatocitari) are ca rezultat accelerarea recuperării funcției re-

nale, prevenind alterarea histologică severă şi scăderea ratei mortalităţii (2,8,11). S-a dovedit că înlăturarea radicalilor liberi, oxigenului reactiv şi moleculelor de nitrogen ar scădea gradul leziunii pe modele animale cu leziune renală acută (11).

- Celulele stem multipotente pot avea rol în promovarea recuperării leziunii renale acute pe modele animale, aşa cum au demonstrat studii recente. În schimb studiile pe oameni au fost larg dezbătute (10,12)

- Există studii cu utilizarea peptidului natriuretic atrial şi IGF1 (11).

Pe modele animale s-a demonstrat că administrarea de magneziu cu N-acetilcisteină protejează rinichiul de efectele IRA postischemice.(14)

În momentul în care diagnosticul de insuficienţă renala este stabilit este oportun să se intervină, intervenţia precoce având impact asupra recuperării.

b. Abordarea terapeutică conservatoare la pacientul pediatric cu leziune renală acută include măsuri simptomatice cum ar fi controlul balanţei fluidelor, managementul dietei şi presiunii sanguine care conduc la îmbunătăţirea timpului de supravieţuire. Încărcarea lichidiană este un factor de risc pentru mortalitate, independent de severitatea bolii. Perturbarea balanţei fluidelor sau metabolismelor necesita adesea iniţierea terapiei de substituţie (5,7).

c. Recentele validări ale criteriilor RIFLE pediatrice au permis revoluţionarea alegerii metodei de abordare a tratamentului de substituţie renalaă (3). Avem pentru prima dată o difiniţie comună care permite compararea seturilor de date între instituţii. Aceasta revoluţionează metoda de abordare a terapiei sustitutive şi ghidează pe viitor studiile făcute la întâmplare.

Exista câteva probleme pe care clinicienii trebuie să le rezolve în momentul în care iau decizie cu privire la modalitatea de supleere renală în insuficienţa renală acută pediatrică:

- stabilirea momentului începerii dializei;

- aprecierea gravităţii bolii şi alegerea metodei care deserveşte cel mai bine nevoile pacientului;

- compararea metodelor disponibile în centrul respectiv;

- expertiza locală pentru stabilirea modalităţii de tratament (5,7).

Având în vedere specificitatea şi caracteristicile pacienţilor, aceştia pot fi trataţi prin hemodializa intermitentă (IHD), dializa peritoneală (DP) sau metode de supleere renală continuă, hemofiltrarea (HF).

Paralel cu schimbarea epidemiologiei s-au produs schimbări dramatice şi în abordarea terapiei de substituţie renală la pacientul cu leziune renală acută.

Datele pediatrice mai recente au sintetizat rezultatele şi au clarificat diagnosticele folosind scorurile de severitate a bolilor şi preconizând intervenţia precoce pentru îmbunătăţirea rezultatelor. Din ce în ce mai multe centre de terapie intensivă sunt echipate cu mijloace de supleere renală, ceea ce le face să devină standardul îngrijirii în astfel de unităţi. În ultima decadă se raportează că HF a devenit prima modalitate de tratament. Alegerea PD, IHD sau HF este dependentă de o varietate de factori, din perspectiva pacientului sau a centrului.

Alegerea celei mai potrivite metode de tratament depinde de statusul clinic al pacientului şi de indicaţiile dialitice. Iniţial trebuie evaluat pacientul, ţinând seama că în insuficienţa organică multiplă se ajunge frecvent şi la insuficienţa renală. Invers, la pacientul care iniţial prezintă leziune renală se poate întâlni şi evoluţie spre insuficienţa organică multiplă.

Indicatorii pentru inițierea tratamentului de supleere includ: modificările electroliților, uremia cu sau fără encefalopatie, hipervolemia cu edem pulmonar, insuficiența respiratorie, intoxicatiile, erorile congenitale de metabolism şi suportul nutrițional.

Factorii ce hotărăsc alegerea celei mai potrivite modalități de terapie:

- caracteristicile pacientului, incluzând vârsta, talia, gravitatea bolii şi comorbiditatile;
- caracteristicile organizatorice, incluzând resursele folosite, tipul instituției, tipul unității de terapie intensivă, tehnica;
- condiția socială a aparținătorilor, înțelegerea costului terapiei.

Indicațiile specifice

Îndepărtarea rapidă din organism a ureei sau corectarea anomaliilor electrolitice (creşterea nivelului potasiului) au o importanță extremă în leziunea renală acută. PD, IHD şi HF pot rapid corecta hiperpotasemia şi uremia (2,5,15).

Epurarea devine urgentă în sindromul de liza tumorală, erorile înnăscute de metabolism, hiperamoniemia, hiperpotasemia simptomatică sau ingestia de toxine dializabile, necesitând PD sau HF. Înlăturarea urgentă a fluidelor este necesară la pacienții cu edem pulmonar sau dificultăți în ventilație, putând fi realizată numai prin IHD sau HF.

La pacienții instabili hemodinamic, cu stări septice, supraîncărcare cu fluide, compromişi respirator, care necesita tratament vasopresor, este preferabil HF pentru controlul statusului fluidelor. Pacienții după intervenții chirurgicale cardiace cu încărcare lichidiană minimă şi instabilitate hemodinamică pot fi mai bine tratați prin PD.

Caracteristicile pacienților

Condiția fizica a pacientului, vârsta, procedurile chirurgicale anterioare şi stabilitatea globală contribuie cel mai adesea la alegerea tratamentului.

Contraindicațiile DP includ: herniile diafragmatice, intervențiile chirurgicale intraabdominale recente, sepsisul şi malignitatile intraabdominale, lezarea suprafeței peritoneului.

Hipotensiunea severă contraindică IHD.

La pacienții nou-născuți, unde accesul vascular este dificil de obținut, se foloseşte PD. La aceştia cateterul poate fi plasat în vasele ombilicale.

Prezența coagulopatiilor face dificil accesul vascular, având impact asupra performanțelor IHD sau HF.

Caracteristici organizatorice

În unele zone geografice, resursele constituie un factor de limitare. PD poate fi suficientă şi alte forme de supleere să nu fie folosite. Abilitatea pentru IHD sau HF depinde de personal şi de experiență.

Considerentele ce pot fi luate în calcul pentru stabilirea unei terapii potrivite vor fi:

- dacă pacientul are nevoie numai de epurare;
- soluția şi numărul de cicluri care pot îndeparta mai multe fluide;
- stabilitatea hemodinamică;
- factorii ce limiteaza condițiile pacientului.

MATERIAL ŞI METODĂ

În Clinica a IV-a de Nefrologie Pediatrica Iaşi în perioada 2003-2008 au fost internate 51 de cazuri diagnosticate cu leziune renală acută conform criteriilor RIFLE pediatrice. Pacienții au fost evaluați atent din punct de vedere clinic şi paraclinic. Parametrii stării de hidratare (tensiune, edeme, greutate, diureză, pierderi extrarenale, aport hidric oral şi parenteral) au fost evaluați zilnic. Retenția azotată şi iono-

grama s-au determinat zilnic în prima etapă şi chiar mai frecvent la bolnavii din terapie intensivă.

Din totalul de 110 pacienți cu IRA, 90 au fost tratați conservator şi 20 au necesitat terapie de substituție renală. Au fost utilizate:

- hemodializa 6 cazuri;
- dializa peritoneală 2 cazuri;
- hemofiltrarea 12 cazuri.

Cauzele ce au determinat leziunea renală acută în cele 20 de cazuri dializate:

TABELUL I

Etiologia la bolnavii tratați prin metode de supleere

Nr. crt.	Cauze	Număr de cazuri	Procente %
1.	SHU	11	55
2.	Disfuncție organică multiplă	4	20
3.	Intoxicații	2	10
4.	Șoc hemoragic	1	5
5.	Necroză corticală	1	5
6.	Glomerulonefrită	1	5

Pe primul loc se situează sindromul hemolitic uremic urmat de disfuncție organică multiplă. Urmărind evoluția cazurilor la bolnavii studiați se remarcă supraviețuire în 16 cazuri şi decese la 4 cazuri. Cauzele deceselor au fost: sepsisul 2 cazuri, hemoragia cerebrală, necroza corticală. Dintre copiii tratați cu hemodializă au decedat 2 şi dintre cei tratați prin hemofiltrare 2. După externare pacienții au fost urmăriți ambulator, la intervale strânse, inițial săptămânal, apoi la o lună, 3 luni, 6 luni, 1 an. După 2 ani au supraviețuit 14 şi 3 au evoluat spre boala renală cronică.

Indicațiile dializei au fost următoarele:

- încărcarea lichidiană cu producerea edemului pulmonar acut sau insuficiența respiratorie - 4 cazuri;
- tulburări metabolice severe: acidoză severă - 5 cazuri, hiperpotasemie - 1 caz, hipernatremie - 1 caz.
- intoxicații: etilenglicol - 1 caz, medicamente dializabile (ciprofloxacin) - 1 caz;
- sângerare - 1 caz
- encefalopatie uremică - 6 cazuri

Dializa peritoneală a fost folosită în 2 cazuri.

Din punct de vedere istoric, PD a fost prima modalitate de terapie substitutivă continuă folosită în unitățile de terapie pediatrică. Mulți clinicieni au avut un grad de confort relativ ridicat prin folosirea acestei terapii. Rapoarte recente din Nigeria, India şi Brazilia au demonstrat în continuare eficiența ei în tratamentul leziunii renale acute pediatrice (5). PD oferă o varietate de avantaje în populația pediatrică cu insuficiență renală acută:

- datorită aspectelor tehnice, accesul a fost rapid şi sigur de obținut, chiar la pacienții cu instabilitate hemodinamică, cum ar fi coagulopatiile.
- s-a realizat cu puțin echipament şi costuri mici.
- se impune în cazul în care nu există IHD sau HF sau în cazul în care există zone rurale sau țări mai puțin dezvoltate;
- PD nu necesită acces vascular iar pacienții în stări critice pot fi dializați cu prezervarea vaselor necesare pentru procedurile viitoare;

Accesul chirurgical în forma clasică plasează cateterul Tenckoff pentru PD în stratul subcutanat la pacienții incapabili să tolereze plasarea chirurgicală, făcând ca terapia să fie rapid instituită. Tehnica a fost bine tolerată de micii pacienți.

Dezavantajele pot include:

- pierderi de dializant în jurul cateterului sau în spațiul pleural, conducând la

hidrotorax;

- infecțiile;

- inițierea unui volum mic de dializat (10mL/kg corp) limitând clearance-ul adecvat.

La copil PD manuală este performantă. Dextroza folosită în PD poate fi o sursă suplimentară de carbohidrați pentru nutriție dar totodată poate conduce la hiperglicemie, necesitând corecție insulinică. Suplimentarea cu natriu şi aminoacizi poate fi necesară.

PD este limitată pentru anumite categorii:

- pacienți cu disfuncție pulmonară la care induce agravarea simptomatologiei prin creşsterea volumului de dializat abdominal;

- pacienți cu şunt ventriculo-peritoneal sau sindrom Prune-Belly, prezentând o creştere a complicațiilor;

- pacienții cu intervenții chirurgicale abdominale nu sunt apți pentru această metodă;

- pierderi semnificative de Ig,cu risc de infecție.

Complicații

- sângerarea;

- peritonitele pot duce la creşterea pierderii de proteine, compromisuri nutriționale, pierderea capacității de ultrafiltrare şi leziuni ale membranei peritoneale;

- complicații mecanice: fisuri, pierderi de lichid, obstrucția cateterului cu cheaguri de fibrină.

Cele mai mari costuri asociate cu PD, în afară de asistentă, sunt cele ale soluției de dializă.

Hemodializa intermitentă

Prezintă avantajul ultrafiltrării rapide. La pacientul stabil hemodinamic este modalitatea cea mai potrivită. Este importantă în intoxicații, sindromul de liză tumorală şi hiperamoniemie întâlnite la populația pediatrică. Exista posibilitatea de a ajusta compoziția dializatului pentru a trata anumite anomalii ale electroliților (hiperpotasemia, hipernatremia) fiind un avantaj major în comparație cu PD sau HF. Este o modalitate valabilă în spitalele mari. Accesul vascular este cel mai important component şi contribuie la realizarea satisfăcătoare a terapiei. Utilizarea venelor cervicale poate fi preferabilă. Amplasarea cateterului poate fi făcută de catre nefrologul pediatru sau de medicul de terapie intensivă.

Accidente care au apărut în cazurile noastre:

- infecția de cateter-septicemie cu bacil cereus - 1 caz;

- hemoragie - 2 cazuri.

Amplasarea cateterului sublavicular ar trebui evitată (pericol de stenoză, făcând imposibilă formarea unei fistule în viitor).

Avantaje :

- rapiditatea înlaturării fluidelor.

Dezavantaje :

- schimbările rapide osmolare conduc la edem cerebral;

- pacienții hipotensivi tolerează rău dializa;

- pacienții non uremici (cu boli congenitale de metabolism şi intoxicații) riscă să prezinte hipofosfatemie.

Hemofiltrarea

Hemofiltrarea a fost instituită la copiii care au beneficiat de supleere renală fără complicații.

În ultimii 5 ani s-au stabilit principiile HF la copii de către un consorțiu pediatric ce cuprinde 13 centre din USA. Consorțiul de Prospectivă Pediatrică (ppCRRT) care a redefinit datele demografice, rezultatele şi stategiile (1,2,5,7). Una dintre cele mai importante variabile a fost gradul de încărcare a pacientului.

Dezavantaje

Cel mai mare dezavantaj al HF este

complexitatea şi pretul crescut comparativ cu cel al PD sau IHD.

Noile aparate folosite au un grad de siguranţăa mai mare, impunând şi creşterea costurilor. Folosirea corectă necesită asistenţă specializată şi suport farmacologic. În ciuda folosirii circuitelor mici în anumite împrejurări, volumul mare extracorporeal necesar pentru HF şi IHD (în particular la nou născuţi) este un dezavantaj major, făcând să fie utilizat la pacienţii peste 10 Kg. Volumul de sânge din circuitul extracorporeal depăşeşte 10 % din volumul de sânge al pacientului. Asociat cu instabilitatea hemodinamică, pacientul are un risc evident. Pacienţii cu insuficienţă organică multiplă pot să nu tolereze HF. Necesită atenţie la tipul hemofiltrului utilizat, datorita reacţiilor bradikininei, activării complementului, cascadei coagulării, degranulării neutrofilelor şi speciilor de oxigen reactive (2,5).

Avantaje

- mimează efectele funcţiei renale, realizând o ultrafiltrare continuă, fiind terapia ideală pentru pacienţii instabili;

- ultrafiltrarea este separată de îndepărtarea soluţiei dializate, oferind mai multă flexibilitate pentru prescripţie, în funcţie de nevoile pacientului;

- îndepărtarea continuă a fluidelor este performantă, permiţând nutriţia adecvată;

- HF poate rapid şi predictibil să restaureze homeostazia;

- HF întreţine controlul uremiei mai bine comparativ cu PD sau IHD;

- înlocuirea filtrului permite clinicianului controlul nivelului de electroliţi; acesta este important în special în hipernatremii, în controlul creşterii presiunii intracraniene precum şi în stările hiperosmolare;

-HF poate avea un beneficiu suplimentar, restaurând homeostazia imunologică, prin îndepărtarea moleculelor proinflamatorii.

În timp ce indicaţiile pentu dializă sunt destul de bine înţelese, datele privind momentele începerii sunt limitate (5,7,15). Consortiul Pediatric de Prospectivă a terapiei de substituţie renală a demonstrat că încărcarea cu fluide constituie un factor de risc important al mortalităţii. Aceasta sugereaza ca intervenţia precoce este esenţială pentru îmbunătăţirea rezultatelor. S-a constatat la copiii cu intervenţii chirurgicale pentru malformaţiile congenitate de cord că PD precoce constituie un avantaj pentru supravieţuire. Aceste date susţin utilizarea intervenţiei înainte de acumularea unei cantităţi semnificative de fluide (> 15% din greutatea corporală).

Pe lângă aceasta, doza de dializă a devenit o variabilă cu importanţă din ce în ce mai mare. Doza de dializă inegală dintre diferitele metode le face dificil de comparat între ele, chiar şi variaţia dozelor în cadrul aceleiaşi metode este subiect de investigat.

Rascue şi colab., în studiile pe adulţi a demonstrat că o doza de 35 mL/Kg/h a fost mai eficientă decat 20 mL/Kg/h pentru supravieţuirea pacientului (8). La pacienţii cu sepsis le-a fost necesară o doză mai mare, 45 mL/Kg/h (5).

Este necesar un scor al severităţii bolii. Swartz a demonstrat că atunci când a fost controlată severitatea bolii, HF a fost superioară IHD în ceea ce priveşte supravieţuirea pacienţilor (16).

CONCLUZII

Utilizarea corectă a mijloacelor de epurare extrarenală contribuie la ameliorarea prognosticului.

Epurarea extrarenală se utilizează in extremis, dupa eşecul terapiei conservatoare.

În centrele cu rezerve limitate, ţelul este optimizarea şi implementarea tratamentului disponibil.

Iniţierea dializei trebuie efectuată precoce, hemofiltrarea fiind superioară celorlalte metode de supleere.

MULTIFACTORIAL ETIOLOGY OF LOWER LIMB EDEMA IN ELDERLY PATIENT WITH HEART FAILURE (Abstract): Aging population and increasing life expectancy has led to an exponential increase in the incidence of heart failure. In the elderly patient with heart failure lower limb edema is most commonly considered in the context of decompensated heart disease, causes such as malnutrition, kidney and liver disease or secondary drug effects being rarer. We report two cases of edema of noncardiac origin. In the first case, kidney damage was identified, edema resulting from hypoproteinemia and proteinuria, and in the second case it had an iatrogenic cause, namely the adverse effect of dihydropyridine calcium channel blocker. In the latter case, investigations centered on the assessment of body composition revealed the tendency to dehydration vs. hyperhydration, which led to a different therapeutic approach compared to the general tendency to administer *per primam* a diuretic treatment. The elderly patient with comorbidities that associate heart failure and lower limb edema requires careful investigations of the possible alternative causes. **Keywords:** ELDERLY, HEART FAILURE, LOWER LIMB EDEMA, MULTIFACTORIAL ETIOLOGY.

Symmetrical lower limb edema is a common clinical sign in the elderly, but also a major problem in geriatric medicine (1). This sign is so common in daily clinical practice because it is the symptom of a wide range of acute or chronic illnesses, and therefore particular attention should be given to the differential diagnosis centered on the elderly patient (2).

The cause of lower limb edema in the geriatric patient is frequently multifactorial (2). Although venous insufficiency and heart failure are the most common causes (3), an important role in this issue is given to protein calorie malnutrition and drug-induced edema: dihydropyridine calcium blockers (4), non-steroid anti-inflammatory drugs (2, 5), corticotherapy.

The general trend in an elderly patient with history of heart failure of various causes and lower limb edema is to establish a causal relationship between them, without further investigation of other causes for edema (6). Therefore, additional systematic investigations are not performed, and patients receive routine diuretic treatment (1), with severe functional and metabolic consequences such as secondary falls (2), renal impairment, hypokalemia, alkalosis and volume depletion.

CASES REPORTS

To exemplify, we report two cases of

elderly patients with heart failure in whom lower limb edema detected on physical examination was due to noncardiac causes.

Case 1. An 81-year-old female the medical history of whom revealed, among others, cardiovascular disorders represented by stage 3 essential hypertension, severe aortic valve stenosis, mild mitral regurgitation and heart failure with preserved ejection fraction. She associated vertiginous syndrome and cervical-lumbar spondylosis. For the afore-mentioned conditions the patient followed drug treatment with loop and anti-aldosterone diuretics (fixed-dose combination of spironolactone 50 mg and furosemide 20 mg), beta blocker (bisoprolol 5 mg), dihydropyridine calcium blocker (Amlodipine 5 mg) and betahistine 24 mg.

The patient presented to a geriatric medical ward with lower limbs edema, declaring the onset of symptoms a month earlier.

The cardiovascular exam showed a 4/6 systolic murmur in the aortic valve area and the echocardiographic examination revealed: normal-size heart, pulmonary artery pressure (PAP=27 mmHg) within normal range, normal inferior vena cava size with inspiratory collapse present and left ventricular ejection fraction (EF)=50%, findings inconsistent with a cardiovascular cause. To rule out iatrogenic-induced edema, treatment with amlodipine was discontinued, but with no result.

Further investigations revealed: high creatinine level corresponding to an eGFR of 44 mL/min/1.73m^2, hypercholesterolemia and hypertriglyceridemia, hypoproteinemia and non-specific inflammatory syndrome (erythrocyte sedimentation rate=130 mm/h). Urine tests were suggestive of glomerular nephrotic syndrome with 24-hours urine protein of 6.48 g.

Considering the diagnostic elements of nephrotic syndrome, further investigations were performed to establish its ethology. In this regard, we investigated a possible immunological (pANCA and cANCA antibodies were negative), and infectious cause (Ag HBs, Ac anti VHC negative), paraneoplastic manifestations - pulmonary, digestive, gynecological, hematological (thoracic X-Ray without suggestive lesions, abdominal ultrasound, kappa to lambda light chain ratio, gynecological examination - within normal limits). In the absence of an obvious cause, renal injury was interpreted in the context of a chronic glomerulopathy secondary to cardiovascular damage, and edema was considered secondary to hypoproteinemia and proteinuria. In addition to cardiovascular medication, maximal antiproteinuric treatment with angiotensin converting enzyme inhibitor was initiated, without diuretic dose adjustment. The outcome was favorable, with lower limb edema and serum proteins correction.

Case 2. An 84-year-old female patient with multiple comorbidities: cardiovascular (stage 3 essential hypertension, paroxysmal atrial fibrillation chemically converted to sinus rhythm, ischemic heart disease), renal (single left kidney after right nephrectomy for kidney tuberculosis), gynecological (total hysterectomy), endocrinological (thyroid nodules and total thyroidectomy) and orthopedic (left hip replacement following femoral neck fracture, right coxarthrosis). The patient followed drug treatment with amiodarone 200 mg/day, amlodipine 10 mg/day, carvedilol 12.5 mg/day, apixaban 2.5 mg x 2/day (adapted to renal function), levothyroxine 100 micrograms/day and alfacalcidiol 0.5 mg/day

(with both metabolic and renal protection due to the antiproteinuric effect).

The patient was symptomatic by dyspnea on low physical exertion, fatigability, and physical examination revealed symmetrical lower limb edema.

Cardiovascular examination showed rhythmic heart beats and blood pressure controlled with the current antihypertensive medication. Chest X-ray showed leftward displacement of the left heart border, right basal pachypleuritis. Transthoracic echocardiography revealed a normal-sized heart with preserved left ventricular systolic function (volumetric EF=57%), delayed relaxation diastolic dysfunction, mild tricuspid regurgitation, normal caliber vena cava, and full inspiratory collapse and moderate pulmonary hypertension (PAPs=60 mm Hg). Clinically, varicose veins were not found, and venous echo Doppler revealed some slightly dilated calf perforator veins.

Blood tests revealed atherogenic dyslipidemia, high creatinine levels (creatinine=1.36 mg% from 1.1 mg% a month earlier), with eGFR of 35.6 mL/min/1.73m^2 from 46.1 mL/min/1.73m^2 a month earlier and normal thyroid status. We did not find any possible cause of the acute deterioration of chronic kidney disease: prerenal (absence of nephrotoxic medication, euvolemic status-determined by bioimpedance), intrinsic renal (urine tests with no pathological findings) and post-renal (absence of ultrasound signs of obstruction and absence of radiographic signs of pelvis compression).

The assessment of body composition by bioimpedance revealed a dehydrated patient, and paradoxically, parenteral hydration was initiated with consequent correction of renal function. Discontinuation of dihydropyridine calcium-channel blocker treatment resulted in remission of edema.

DISCUSSION

The diagnosis of heart failure in the elderly can be difficult due to the increased prevalence of atypical signs and symptoms, presence of concomitant diseases (they may alter the classic manifestations of heart failure) and, on the other hand, due to the different perceptions of patients on the changes usually associated with it (7). Confusion, delirium, cognitive deficit, physical and mental asthenia which are a characteristic of the elderly can alter the symptoms or even mask them completely (8).

In the geriatric population, heart failure is the second most common cause of symmetrical lower limb edema after venous insufficiency (1); this aspect is due to the increased incidence of heart failure with preserved ejection fraction of up to 50% (3), being consistent with the two reported cases.

Among the most common - and less investigated - comorbidities in the elderly patients with heart failure are renal dysfunction, frailty and malnutrition (9, 10), polypragmasy and drug-induced edema (6, 11), lower limb edema being a common symptom of these entities (12). The systematic investigation of these entities will lead to a correct identification of the causes for edema onset, avoiding inappropriate administration and disastrous results of diuretic treatment, most commonly injectable furosemide.

In the first presented case, further investigations revealed the presence of a nephrotic syndrome, superimposed on preexisting heart disease. Considering the wide range of nephrotic syndrome causes, exhaustive parallel investigations were

required to avoid omitting a possible causal treatment. Chronic glomerulopathy is a common clinical syndrome in the elderly with chronic kidney disease (13), and this is the type of kidney damage identified in the first reported case.

Another important aspect is the iatrogenic cause of lower limb edema in the elderly. The incidence of drug-induced edema is seriously underestimated (1). Among the incriminated agents, antihypertensive drugs (3) and non-steroidal anti-inflammatory drugs (2) are the most common drugs. It is estimated that 50% of patients receiving dihydropyridine calcium channel blockers develop lower limb edema at different times of treatment (1). Our second case illustrates the situation of amlodipine-induced edema in a patient with stable cardiac failure and concomitant kidney disease. For the accuracy of the diagnosis in this case, the data in the literature demonstrate the superiority of bioimpedance versus clinical assessment (14).

Pulmonary hypertension is an underdiagnosed cause of lower limb edema, especially in the elderly patients. The substrate is sleep apnea, but it can also be secondary to chronic lung disease (1). The echocardiographic assessment in the second reported case revealed moderate pulmonary hypertension, which confirms the frequently multifactorial etiology of lower limb edema in the elderly patient (15).

CONCLUSIONS

In our cases, strict investigation of alternative causes of lower limb edema in the elderly is therefore necessary, beginning with the most common causes such as heart failure, protein-calorie malnutrition, to the least frequent, represented by iatrogenic cause, nephrotic syndrome and pulmonary hypertension. This strategy may reduce diagnostic confusion and may also reduce inappropriate use of diuretics with severe consequences: renal damage, dehydration, hyponatremia/dyselectrolytemia, increased risk of falls and poor life quality.

A direct consequence of this phenomenon is the increased number of patients experiencing symmetrical lower limb edema, the investigation of this clinical sign being a major but neglected problem of geriatric medicine due to its frequently non-cardiac and often multifactorial etiology.

NEWS

IMPACT OF LEFT VENTRICULAR DIASTOLIC DYSFUNCTION ON LUNG TRANSPLANTATION

Diastolic dysfunction may influence perioperative outcome, early graft function, and long-term survival. Has been compared the outcomes of double lung transplantation (DLTx) for patients with pulmonary arterial hypertension (PAH) with preoperative left ventricular (LV) diastolic dysfunction with the outcomes of patients without diastolic dysfunction. Fourteen (31.8%) patients with diastolic dysfunction pretransplantation had a higher body mass index (29 [IQR 21.5-32.6] vs 22.4 [IQR 19.9-25.3] kg/m^2) and mean pulmonary arterial pressure (54.6 10 mmHg vs 47 +/- 11.3 mmHg) and right atrial pressure (16.5 +/- 5.2 mmHg vs 10.6 +/- 5.2 mmHg). The patients received extracorporeal life support more frequently, had worse APACHE II scores, and a trend toward worse ventilator-free days. In conclusion, diastolic dysfunction was the only variable that correlated with overall survival and leads to early postoperative morbidity and worse survival in patients with PAH after DLTx (Avriel A, Klement A, Johnson S, *et. al*. Impact of Left Ventricular Diastolic Dysfunction on Lung Transplantation Outcome in Patients with Pulmonary Arterial Hypertension, *American Journal of Transplantation* 2017; 17(10): 2705-2711).

CORRELATION BETWEEN ESSENTIAL HYPERTENSION AND CAROTID INTIMA MEDIA THICKNESS IN CHILDREN (Abstract): Essential hypertension is no longer un uncommon disease in children. This study try to determine if carotid intima thickness is increased in children with essential hypertension. **Material and method**: This subjects are compared with control group with normal blood pressure. The study group consists of 78 children with essential hypertension; there were excluded cases with secondary hypertension. These children had carotid intima media thickness, left ventricular mass index and body mass index performed. In control group there were 53 subjects and there were performed the same investigations for them. **Results**: Sixtyfour cases (82,05%) from study group had obesity (body mass index ≥ 85 percentile). Left ventricular mass index was increased in 40 cases (51,28%). Increased carotid intima media thickness was found in fiftyone subjects (65,38%) in the group of hypertensive children and it range between 0,52 şi 0,69 mm. In the control group carotid intima media thickness varies between 0,32 şi 0,54 mm. The carotid intima media thickness correlated with sistolic blood pressure(P=0,00000), with diastolic blood pressure (p=0,000002), with body mass index (p=0,00000) and with body mass index(p= 0,000001). **Conclusion**: The study could not state if increased carotid intima media thickness is due to hypertension or to obesity, because in children there is a strong association between these two diseases. Anyway, evaluation of this parameter may offer information about early endothelial disfunction. **Key words**: ESSENTIAL HYPERTENSION, CAROTID INTIMA MEDIA THICKNESS, ENDOTHELIAL DISFUNCTION

Incidenţa hipertensiunii arteriale esenţiale (HTAE) la copil este în creştere, pragul vârstei de debut coborând spre vârsta de 10-12 ani (1) . HTAE reprezintă un factor de risc major pentru dezvoltarea aterosclerozei şi a patologiei coronariene la adult. Se consideră că acest risc exista la valori ale tensiunii arteriale (TA) de 115/75 mm Hg şi se dublează cu fiecare creştere cu 20/10 mm Hg acesteia (2). Între HTA şi activitatea endoteliului vascular există o relaţie cauză-efect în ambele direcţii. Pe de o parte, presiunea arterială constatant crescută determină disfuncţie endotelială consecutivă, cu modificări funcţionale si structurale la nivelul vaselor (3). Pe de altă parte, disfuncţia endoteliului vascular contribuie la progresia HTA (4). Mai mult, nu trebuie ignorat faptul că la copil, obezitatea se asociază frecvent cu hipertensiunea arterială .Una dintre cele mai precoce modificări caracteristice acestei asociatii o reprezintă dis-

funcţia endotelială şi aparitia plăcilor aterosclerotice evidenţiate chiar de la vârsta de 2 ani (5). Modificările structurale de la nivelul arterelor carotide pot fi puse în evidenţă cu ajutorul ecografiei Doppler prin măsurarea grosimii intimă-medie la artera carotidă (IMTc). În studiul de faţă ne-am propus să determinăm corelaţia între hipertensiunea arterială esenţială şi valoarea crescută a IMTc precum şi în ce măsură IMTc crescută se datorează HTA sau obezităţii.

MATERIAL ŞI METODĂ

Caracteristicile clinice

Au fost incluşi în studiu 78 pacienţi internaţi la Spitalul Clinic de Copii Braşov, în perioada ianuarie 2007 – noiembrie 2009, care au fost diagnosticaţi cu hipertensiune arterială. Toţi subiecţii aveau valori ale TA sistolice şi/sau diastolice mai mari de percentila 95 pentru vârstă, sex şi înălţime, confirmate la cel puţin 3 determinări separate, la interval de 2 săptămâni. Nu au fost incluşi în lotul de studiu pacienţii la care au fost identificate cauze secundare de HTA.

Lotul martor a fost alcătuit din 53 de subiecţi cu TA sistolică şi diastolică sub percentila 90 pentru vârstă, sex şi înălţime, la minim 2 determinări separate.

În ambele loturi am măsurat greutatea şi talia şi am calculat indicele de masă corporală (IMC) conform formulei $IMC = G/T^2$ (unde G= greutatea, exprimată în kg, T= talia, exprimată în metri). Tensiunea aterială a fost măsurată respectând recomandările "Celui de al 4-lea raport privind diagnosticul, evaluarea şi tratamentul hipertensiunii arteriale la copil şi adolescent"(6).

Ecocardiografia

Atât la subiecţii cuprinşi în lotul de studiu cât şi la cei din lotul martor s-a efectuat ecocardiografie 2D, mode M şi examen Doppler (ecograf marca Fukuda). Nici un pacient nu a fost diagnosticat cu coarctaţie de aortă sau cu alte anomalii structurale cardiace. La examenul ecocardiografic s-a urmărit depistarea hipertrofiei VS (HVS), considerată ca fiind cea mai frecventă complicaţie a HTA primare la copil. Masa ventriculului stâng (VS) a fost calculată pe baza formulei (6):

$$\textbf{Masa VS (g)} = 0{,}80\,[1{,}04\,(\text{SIV}+\text{DED-VS}+\text{PP-VS})^3-(\text{DED-VS})^3]+0{,}6$$

unde: SIV = septul interventricular, DED-VS = diametrul end-diastolic al VS, PP-VS = peretele posterior al VS

Pentru evaluarea HVS s-a calculat masa ventriculului stâng care a fost indexată cu înălţimea pentru a face corecţia cu suprafaţa corporală. HVS este definită de valori

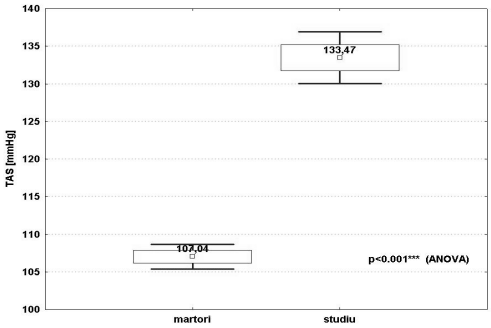

Fig. 1. Variaţia TAS la lotul studiu şi lotul martor

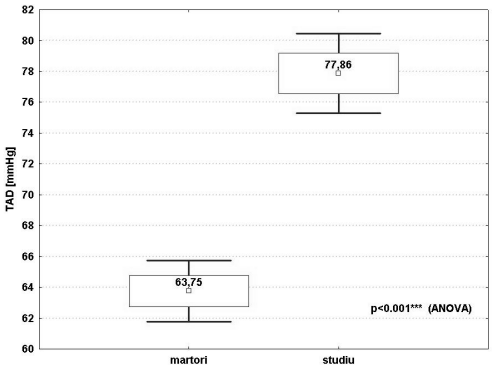

Fig. 2. Variaţia TAD la lotul studiu şi lotul martor

ale indicelui masei VS mai mari de percentila 95, adică, pentru băieţi ≥ 39,36 g/m^2 iar pentru fete ≥ 36,88 g/m^2 (7).

Ecografia Doppler a arterelor carotide

Am determinat grosimea intimă-medie la artera carotidă atât la subiecţii incluşi în lotul de studiu, cu HTA, cât şi la subiecţii din lotul martor. Am folosit ecograful marca Fukuda, iar examinarea s-a efectuat cu transductor liniar cu frecvenţa de 12,5-13 MHz. Subiecţii au fost examinaţi într-un mediu ambiental liniştit, cu confort termic, fără zgomote, după un repaus prealabil de 15 minute. Poziţia de examinare a fost în clinostatism, cu faţa în sus şi capul rotit la 45° de parte opusă arterei examinate. Am efectuat manual câte 5 măsurători pentru fiecare perete (anterior şi posterior), pe o distanţă de 1 cm, pentru artera carotidă dreaptă şi stângă iar în studiu s-a utilizat media aritmetică a valorilor obţinute. Acestea au fost comparate cu valorile considerate normale pe grupe de vârstă (8).

Analiza statistică: am folosit pentru calculul statistic metoda ANOVA pe care am aplicat-o pentru variabilele continue şi testul chi pătrat pentru compararea grupurilor. Am considerat semnificativă statistic valoarea $p < 0,05$.

REZULTATE

Lotul studiu a cuprins 78 de pacienţi la care s-a stabilit diagnosticul de HTA primară. Dintre aceştia, au fost 46 băieţi (58,97%) şi 32 fete (41,02%). Vârstele subiecţilor au variat între 5,9 ani şi 17,11 ani (media de vârstă 13,67 ani). Lotul martor a cuprins 53 de subiecţi, cu 25 băieţi (47,16 %) şi 28 fete (52,83%), cu vârste cuprinse între 5,7 şi 17,10 ani (media de vârstă 14,07 ani). În lotul de studiu, 55 de copii (70,51%) prezentau şi obezitate (IMC > percentila 95), 9 copii (11,53%) erau supraponderali (IMC cuprins între percentila 85 şi 95) iar 14 (17,94%) au fost normoponderali (IMC < 85). În lotul martor 3 subiecţi (1,88%) au fost supraponderali (IMC cuprins între percentilele 85 şi 95) şi 18 subiecţi (33,96%) au fost obezi (IMC > percentila 95). Caracteristicile demografice şi clinice sunt prezentate în tabelul I. Valorile TAS şi TAD în cele două loturi este reprezentată în figurile 1 şi 2. Se observă o diferenţă semnificativă între cele două grupuri; 44 subiecţi (56,41%) din lotul studiu au valori ale TA > percentila 99 pentru vârstă, sex şi talie, ceea ce demonstrează instalarea formelor severe de HTAE încă de la vârstă mică. Ecocardiografia a pus în evidenţă la pacienţii hipertensivi (valori ale TAS şi/sau TAD > percentila 99) prezenţa hipertrofiei VS în 40 de cazuri (51,28%). Urmărind IMTc, am observat că aceasta se corelează pozitiv cu HTA (fig. 3), ea fiind semnificativ crescută la subiecţii hipertensivi faţă de cei

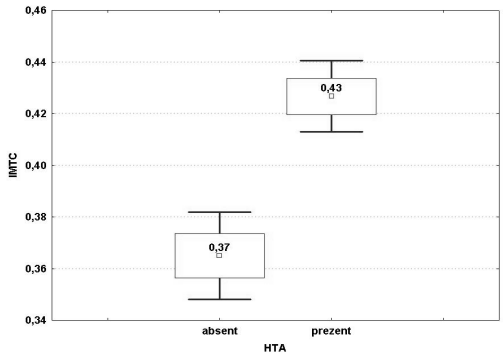

Fig. 3. Corelaţia HTA - IMTc

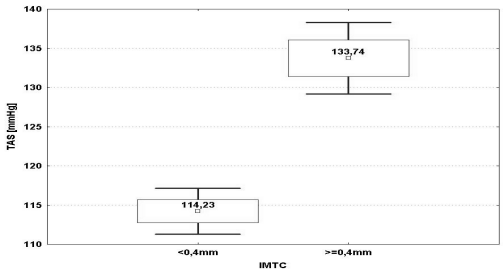

Fig. 5. Variaţia IMTc cu TAS

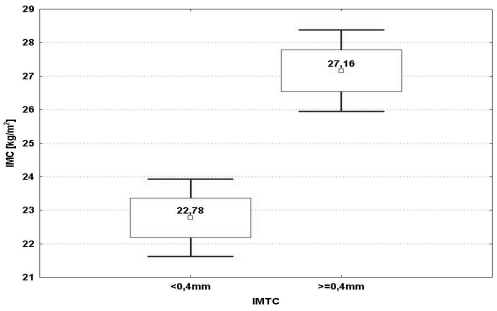

Fig. 4. Variaţia IMTc în funcţie de IMC

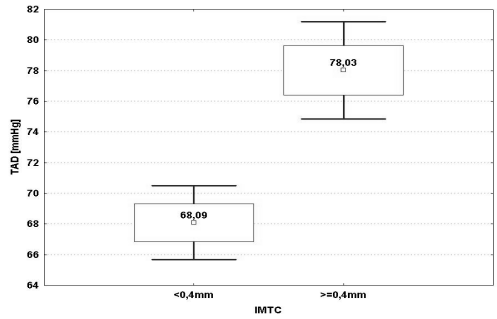

Fig. 6. Variaţia IMTc cu TAD

normotensivi. În lotul studiu IMTc a variat între 0,52 şi 0,69 mm iar pentru subiecţii normotensivi limitele au fost de 0,32 şi 0,54 mm. Toţi subiecţii hipertensivi care au avut HVS au prezentat şi IMTc crescută. 18 subiecţi hipertensivi si obezi(IMC > 95th) nu au avut HVS dar au avut IMTc crescută. De aceea am considerat creşterea grosimii intimă-medie a carotidei ca o consecinţă a obezităţii şi a proceselor aterosclerotice şi nu a hipertensiunii arteriale. Atât în lotul de studiu cât şi în lotul martor, la pacienţii cu obezitate, s-a depistat raport crescut intimă-medie la artera carotidă comună, ceea ce înseamnă că IMTc s-a corelat pozitiv cu IMC (p= 0,000001) (fig. 4). În lotul subiecţilor hipertensivi am constatat că există o corelaţie pozitivă între IMTc şi valorile TAS (p=0,0001) (fig. 5) şi TAD (p=0,0001) (fig. 6). Pacienţii cu valori ale TAS şi TAD mai mari de percentila 99 au fost cei care au prezentat cele mai severe modificări ale raportului intimă-medie (valori mai mari 0,5 mm), probabil, ca o consecinţă asupra peretelui arterial a regimului presional crescut. În mod cert şi-a adus contribuţia şi factorul timp la modificarea IMTc, deoarece la aceşti subiecţi era prezentă şi HVS, dovada unei evoluţii în timp a HTA. Astfel, am constatat că IMTc s-a corelat pozitiv cu indexul masei VS (p=0,0001) (fig. 7).

În lotul martor, 7 subiecţi au prezentat IMTc crescută aceştia fiind normotensivi dar obezi (IMC > 95th) fapt ce sugerează că aceasta este consecinţa modificărilor aterosclerotice.

DISCUŢII

În studiul nostru, vârsta de debut a HTAE a fost între 10 ani şi 17 ani la 69 subiecţi (88,46%) dar, 9 subiecţi (11,53%) aveau vârste cuprinse între 6 şi 10 ani când au fost diagnosticaţi cu HTAE. Cu toate că procentul este mic şi nesemnificativ statistic, trebuie să subliniem vârsta mică la care a debutat boala. Şi în literatura de specialitate

se fac referiri legate de coborârea vârstei de debut sub 10-12 ani. Un număr semnificativ de subiecţi au prezentat valori crescute ale TA şi afectarea „organelor ţintă" (HVS şi IMTc crescută) fapt ce permite încadrarea HTA în stadii avansate şi indică o evoluţie anterioară de cel puţin 6 luni. Procesele patologice care se produc la nivelul peretelui arterial, consecinţe ale regimului presional ridicat, pot să fie puse în evidenţă cu ajutorul ecografiei Doppler, prin măsurarea grosimii intimă-medie arterială. Creşterea indicelui intimă-medie este dovada modificărilor structurale produse la nivelul peretelui arterial. Am aplicat în studiul de faţă această metodă şi am reuşit să punem în evidenţă prezenţa acestor modificări structurale arteriale. Astfel, am găsit că valoarea IMTc este mai crescută la copiii cu hipertensiune arterială primară faţă de copiii cu valori normale ale TA şi că această valoare se corelează pozitv cu valorile TAS şi TAD. În cadrul lotului cu subiecţi hipertensivi valoarea IMTc a fost crescută atât la cei obezi cât şi la cei normoponderali, ceea ce demonsterază că regimul de presiune sanguină ridicată poate determina în timp modificări vasculare structurale. Pe de altă parte nu putem ignora faptul că, în studiul nostru, proporţia subiecţilor obezi a fost semnificativă atât în grupul hipertensivilor cât şi în grupul normotensivilor. Aceştia au avut, deasemenea, IMTc crescută, corelată pozitiv cu IMC. Se observa astfel o asociere strânsă între obezitate şi creşterea IMTc (9,10) şi de aceea, este dificil de precizat în ce măsură, la apariţia ei au contribuit HTA sau obezitatea. Este posibil ca modificările structurale ale endoteliului vascular să fie datorate obezităţii şi ele să fi precedat şi detreminat instalarea HTA. Ar fi interesant extinderea studiului pentru a urmări subiecţii hipertensivi şi obezi, cei hipertensivi dar fără obezitate şi cei obezi dar fără hipertensiune arterială, pe o perioadă mai lungă de timp, pentru a vedea în

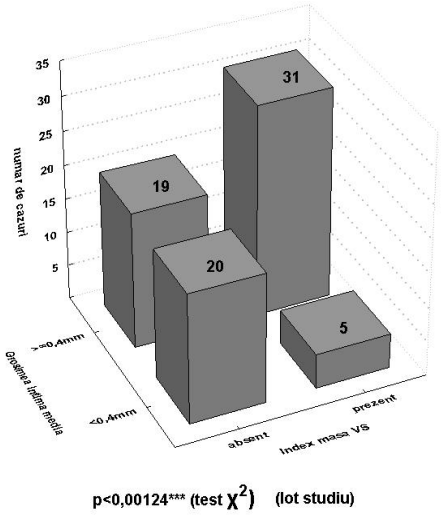

Fig. 7. Corelaţia IMTc cu indexul masei VS în lotul de studiu

ce măsură modificările prezente în copilărie (HTA, obezitatea, disfuncţia endotelială) sunt predictibile pentru evenimentele cardiovasculare din viaţa adultă. De asemenea, ar putea prezenta interes studiere indicatorilor funcţionali vasculari cum sunt distensibilitatea vasculară, geometria arterială coronariană dar şi vasodilataţia mediată de flux.

CONCLUZII

HTA esenţială este prezentă la copil. Raportul intimă-medie crescut corelează cu HTA şi este un indicator al modificărilor structurale endoteliale secundare regimului presional crescut. Deoarece un procent semnificativ din populaţia pediatrică cu HTA studiată a asociat şi obezitate, nu se poate afirma cu certitudine că alterările vasculare se datorează exclusiv HTA. Determinarea raportului intimă-medie prin ultrasonografia Doppler este o metodă accesibilă, neinvazivă, uşor reproductibilă care poate oferi date utile despre procesele structurale de la nivelul arterelor chiar înainte de apariţia semnelor clinice de afectare organică datorată HTA.

RESPIRATORY FEATURES OF A SYSTEMIC LUPUS ERYTHEMATOSUS IN A SMOKING PATIENT. CASE REPORT (Abstract): There is increasingly mentioned in literature a respiratory onset of the systemic lupus erythematous (SLE). A 61-year-old female (active smoker, with myocardial infarction history) was admitted in the hospital for respiratory failure, fatigue, nose rash, alopecia, photosensitivity, polyarthralgia, weight loss. Computed Tomography (CT) scan of the chest noticed a pattern of an obliterative bronchiolitis ("tree-in-bud", interstitial fibrosis, and bronchiectasis), kyphosis and advanced atherosclerosis. Immunological investigation revealed antinuclear antibodies that sustained SLE diagnosis. Lung function impairment showed severe mixed ventilatory dysfunction with decreased oxygen saturation (SaO2) below 90% during a minimal effort. Bronchoscopy, chest CT and biomarkers excluded sarcoidosis or lung tumor. Skin biopsy confirmed SLE vasculitis. The patient received immunosuppressive medication, oxygen, bronchodilators, vasoactive agents, platelet aggregation inhibitors, statins. Clinical status improved after 2 weeks and stabilized after 1 year under treatment. SLE may have a long less symptomatic evolution and could evolve apparently subacute with respiratory features. The previous myocardial infarction and the advanced atherosclerosis may be considered early manifestations of SLE vasculitis in a smoker. Early education for smoking cessation in patients with ischemic condition has to be part from the rehabilitation program for respiratory and cardiovascular complication prevention. **Keywords**: SYSTEMIC LUPUS ERYTHEMATOUS, OBLITERATIVE BRONCHIOLITIS, SMOKING.

Systemic lupus erythematosus (SLE) is a severe autoimmune disease with poly visceropathy affecting multiple organs: skin, kidney, vessels, spleen, liver, joints, lungs and the nervous system. The lungs are commonly involved later in the disease evolution with common features: pleural effusion, interstitial lung fibrosis, vasculitis, diaphragmatic dysfunction and upper airway dysfunction (1, 2, 3, 4). The pattern of interstitial fibrosis with obliterative bronchiolitis (OB) is rarely met but possible (less than 5% in SLE) (5). This form of lung involvement in SLE associates obstructive/mixed ventilatory disorder, asthma like symptoms and are close linked with smoking (6, 7, 8). It is well known that smoking by itself is a main risk factor for

various chronic respiratory diseases: chronic bronchitis, idiopathic fibrosis, collagen diseases, tuberculosis and sleep apnea (6, 8, 9). There is increasingly mentioned in literature the late-onset of SLE while clinical/serological aspect seems to be more atypical. In this context, SLE may be considered in people (especially women) of more advanced age starting from any clinical presentations compatible with the disease (10). The case report reviews the particularities of the clinical aspect, pulmonary manifestations of SLE, investigation, and their contribution in SLE diagnosis.

CASE REPORT

We present the case of a late SLE onset in a 61-year-old female patient (active smoker and occupational exposure to chemicals) with a history of pulmonary tuberculosis (PTB) in 2000 and a myocardial infarction in 2008 (minimally treated after the acute episode). The patient was admitted in the Pulmonology Clinic with symptoms began in the last 2 weeks: wheezing, intermittent purulent cough, progressive respiratory failure with rest dyspnea and cyanosis, nose and malar rash, alopecia, asthenia, weight loss, polyarthralgia and diffuse crackles. The chest x-ray revealed a diffuse interstitial fibrosis. Thoracic High Resolution Computed Tomography (HRCT) confirmed the fibrosis and revealed an aspect of obliterate bronchiolitis (OB): "tree-in-bud" bronchioles, centrilobular micronodules (by bronchiolar inflammation and mucus plug), bronchiectasis and air trapping with "mosaic" pattern (fig. 1. a.). Computed Tomography (CT) of the chest excluded lung tumor or pleural complication. Sagittal CT section showed kyphosis and diffuses atherosclerosis of the thoracic and abdominal aorta (fig. 1.b.).

Fig. 1. a. Chest CT: a. Interstitial fibrosis, obliterative bronchiolitis ("tree-in-bud" aspect of bronchioles, centrilobular micronodules) and bronchiectasis.
b. Kyphosis, osteoporosis, advanced diffuse atherosclerosis of the aorta.

Lung function evaluated by spirometry indicated a mixed ventilatory dysfunction with a severe obstructive pattern with forced vital capacity (FVC) of 1.74L (67.9%), forced expiratory flow in 1 second (FEV-1) of 1L (48.7%) and ratio FEV1/FVC of 60.2%. Carbon monoxide diffusing capacity (DLCO) was very low

(57%) and decreased oxygen saturation (SaO2) below 90% during a minimal effort to 86%.

Electrocardiography (ECG) showed an atrial tachycardia, diffuse ischemic changes and sequela of right ventricle myocardial infarction. Transthoracic echocardiogram showed multiples aortic atheroma, right ventricle dilatation and moderate pulmonary hypertension.

Bronchoscopy evidenced a chronic bronchitis, diffuses bronchiectasis and excluded sarcoidosis (negative bronchial biopsy) or a central lung tumor.

Bacteriological investigation performed from bronchoalveolar lavage was negative for Koch bacilli in microscopy and culture, negative for fungi, but positive for the opportunistic infection Pseudomonas aeruginosa.

Several immunological, serological analysis for SLE confirmation were performed revealing low value of C3 Complement (43mg/dl), negative results for anti-neutrophil cytoplasmic autoantibodies (ANCA), serum angiotensin-convertase enzyme, rheumatoid factor, anti-centromere and anti-scl70/anti-topoisomerase antibodies; and positive results for the antinuclear antibodies (ANA) titer (1:40), antibodies anti-double stranded DNA (dsDNA antibodies), anti-Smith antigen, as well as positive cardiolipin antibodies cLA (56 units GPL IgG phospholipid antibodies). Other blood tests revealed mild anemia (Hb-9.86g%, Htc-34%) with reticulocytosis, negative HIV test and anti-streptolysin O antibodies.

The skin biopsy of the scalp confirmed the presence of vasculitis in the context of SLE and permitted differentiation with other lesion: sarcoidosis or “alopecia areata”.

The final diagnosis included SLE (malar and nasal rash, unusual loss of hair, polyarthritis, ANA and dsDNA antibodies, anemia, vasculitis) associated with bronchiolitis obliterans, diffuse lung fibrosis, diffused over-infected bronchiectasis (with Pseudomonas aeruginosa), respiratory failure, moderate secondary pulmonary hypertension, advanced aortic atherosclerosis and ischemic heart disease with sequela of myocardial infarction, mild anemia, dorsal kyphosis, depression and active smoking. The patient was referred to rheumatology and cardiology for further investigations, therapy and monitoring. Under 2 weeks of hospitalization and therapy with immunosuppressive drugs (azathioprine), long term home oxygen, inhaled corticosteroids and long acting-βagonists bronchodilators, vasoactive agents, platelet aggregation inhibitors, statins and antibiotics (fluoroquinolones administered for 10 days), clinical status improved. After 1 year, the patient was stable under chronic treatment.

DISCUSSION

In our reported case, SLE had a slow clinical course with very few symptoms and an apparently late subacute onset with respiratory failure by lung fibrosis and obliterative bronchiolitis (OB) (the diagnostic of SLE was performed in the Pulmonology Clinic). The rheumatologic examination confirmed the suspicion of SLE according to the American College of Rheumatology (ACR) and Systemic Lupus International Collaborating Clinics (SLICC) revised criteria (11). Studies revealed that 3% of SLE cases may occur with respiratory symptoms and have a pattern of obliterative bronchiolitis at the clinical presentation (12). The particularities of SLE with OB and lung fibrosis may be

explained by smoking history and professional exposure (6, 7, 13). So, the risk of lung cancer must be considered in the future (14). The interstitial fibrosis with over infected bronchiectasis evoques a long-time subclinical evolution and an immunodeficient status within the collagen disease. Decreased immunity in association with biological therapy can induced an increased risk of tuberculosis among patients with previous PTB and collagen disease (4,12). OB is a chronic inflammation of the small bronchioles with wall thickening and polypoid proliferation, cell debris, lymphocytic infiltration and peribronchial fibrosis (5) and it may have very heterogeneous causes as viral infections (e. g. respiratory syncytial virus, cytomegalovirus, human immunodeficiency virus), exposure to toxic dust, fumes or drugs (including smoking), collagen diseases, chronic rejection in lung transplantation, primary biliary cirrhosis, some asthma or Chronic Obstructive Pulmonary Disease phenotypes, cystic fibrosis (2, 3, 5, 6, 7, 12). In this reported case, the criteria for OB diagnosis were clinical context of a severe dyspnea in a middle-aged smoker woman, specific HRCT details (hyperinflation, bronchiolar thickening, micronodules, "mosaic" perfusion, diffuse interstitial fibrosis, bronchioles pattern type "tree-in-bud"), severe mixed ventilatory impairment and decreased DLCO. The impact of occupational exposure to chemical products, on lung function, is difficult to evaluate especially related to smoking (1, 2, 6, 7, 14).

The acute coronary accident noticed in the medical history and the advanced aortic atherosclerosis may be considered in relation to smoking and underlying disease. Several studies have established the correlation between SLE and atherosclerosis that is accelerated by the autoimmune vasculitis (15). In this context the treatment with statins was recommended like an immunomodulators of an inflammatory phenomenon (16).

Smoking is an important contributive risk factor that aggravated in the same time fibrosis, obstructive bronchiolitis and vasculitis. Promoting consistent antismoking education would have been required in this case much earlier, especially after the myocardial infarction (17,18). Histopathology from skin biopsy and serologic tests contributed to the diagnosis of vasculitis within SLE and to the differential diagnosis with sarcoidosis or other well-defined vasculitis (19, 20). Vasculitis can be a rare manifestation of tuberculosis or tuberculosis can associate with vasculitis (21). Heavy smoking associated with a collagen disease, as rheumatoid arthritis, can evoques even tuberculosis or lung cancer (22). Bacteriology from bronchoalveolar lavage permitted the diagnosis of the bacterial colonization of bronchiectasis, antibiotic susceptibility test and the targeted antibiotic treatment. Considering the risk of tuberculosis in Romania (22), bacteriological screening must be performed. Negative microscopy for acid fast bacilli stain and cultures for Koch bacilli and nontuberculous mycobacteria excluded tuberculosis and mycobacteria (2-10% prevalence met in immunodeficient patients) (23).

CONCLUSIONS

Our case is distinguished by delayed diagnosing of SLE in a Pulmonology Department. SLE may have a long-time mild symptom masked by a progressive respiratory failure. Vascular and skin main involvement of the SLE did not associated with renal and/or nervous manifestations.

The respiratory features of obliterative bronchiolitis and lung fibrosis allowed the necessity of an urgent broad immunologic investigation for underling collagen disease. The previous early myocardial infarction, round 50-year-old, and the advanced atherosclerosis could be considered in relation both with SLE vasculitis and chronic smoking.

According to the medical history and comorbidities, a close medical surveillance and sustained treatment are required. Early education for smoking cessation in patients with respiratory and vascular ischemic poor condition has to be a main component of a rehabilitation program for preventing the respiratory and cardiovascular complications.

LIPIDOMES OF LUNG CANCER AND TUMOUR-FREE LUNG TISSUES REVEAL DISTINCT MOLECULAR SIGNATURES FOR CANCER DIFFERENTIATION, AGE, INFLAMMATION, AND PULMONARY EMPHYSEMA

The study highlights how health status might be mirrored in the lung lipidome. Little is known about the human lung lipidome, its variability in different physiological states, its alterations during carcinogenesis and the development of pulmonary emphysema. Tissues were sampled for both lipidomic and histological analysis. Using a screening approach, were characterized lipidomes of lung cancer tissues and corresponding tumor-free alveolar tissues. Tumor tissues exhibited elevated levels of triacylglycerols and cholesteryl esters, as well as a significantly lower abundance of phosphatidylglycerols, which are typical lung surfactant components. Adenocarcinomas and squamous cell carcinomas were distinguished with high specificity based on lipid panels. Lipidomes of tumor biopsy samples showed clear changes depending on their histology and, in particular, their proportion of active tumor cells and stroma. Partial least squares regression showed correlations between lipid profiles of tumor-free alveolar tissues and the degree of emphysema, inflammation status, and the age of patients. Unsaturated long-chain phosphatidylserines and phosphatidyl inositol showed a positive correlation with a worsened emphysema status and ageing. This work provides a resource for the human lung lipidome and a systematic data analysis strategy to link clinical characteristics and histology (Eggers LF, Müller J, Marella C *et al*. Lipidomes of lung cancer and tumor-free lung tissues reveal distinct molecular signatures for cancer differentiation, age, inflammation, and pulmonary emphysema. *Scientific Reports* 7, 2017).

GERM CIRCULATION IN NEONATAL UNITS – RISK FACTORS FOR MATERNAL--FOETAL INFECTION (Abstract) Infections are the third most important cause of morbidity and mortality in neonatal units. Infection rates are 2-5% in I-II level units, 10% in IIIrd level units and 7-24% in NICUs. **Aim**: To identify risk factors contributing to maternal-foetal and hospital infections in neonatal units of different levels in two maternity hospitals in Romania: Buna Vestire Obstetrics and Gynaecology Hospital in Galati (Lot A) and Cuza-Voda Obstetrics and Gynaecology Hospital in Iasi (Lot B). **Material and methods**: This is a retrospective and prospective study during four years in two neonatal units in maternity hospitals of different levels from Moldova: level II – Lot A and level III – Lot B. **Results**: Neonatal infection rates were significantly higher in preemies compared to term newborns (5.91% - Lot A vs. 9.9% - Lot B). Predominant maternal colonization and infection bacteria were *E. coli* (16.12% - Lot A vs. 12.6% - Lot B) and *S. aureus* (1.3% - Lot A vs. 2.03% - Lot B). Personnel colonization, predominantly with MRSA, presented little hazard for neonatal infection (RR 0.9 – Lot A, RR 0.7 – Lot B). Hospital environment contamination also presented minor risk for neonatal infection (RR 1.7 – Lot A, RR 0.2 – Lot B). **Conclusions**: The main risk factors for neonatal infections were gestational age (premature infants have immunological underdevelopment) and maternal colonization. Personnel colonization and hospital contamination are of little importance in the development of neonatal infections. **Key words**: NEONATAL INFECTION, MATERNAL COLONIZATION, GESTATIONAL AGE, HOSPITAL ENVIRONMENT CONTAMINATION

Infecţiile sunt a treia cauză de morbiditate şi mortalitate în secţiile de nou-născut (1). Rata infecţiilor diferă în funcţie de nivelul secţiei (nivel I-II comparativ cu secţiile de nou-născuţi de nivel III şi terapie intensivă neonatală). Astfel, rata de infecţie în secţiile de nivel I-II este de 2-5%, 10% în secţiile de nivel III şi între 7-24% în secţiile de terapie intensivă neonatală (TIN) (2,3). Factorii majori implicaţi în producerea infecţiilor materno-fetale şi nosocomiale ţin în special de gazdă care este nou-născutul la termen şi mai ales prematur (imaturitate imunologică), de gravidă şi lehuză colonizată cu germeni gram negativi sau pozitivi, de condiţiile de îngrijire în secţiile de nou-născuţi normali (supraaglomerare, circuite inadecvate, personal insuficient) şi terapie intensivă neonatală (proceduri diagnostice şi terapeutice, ventilaţie mecanică, alimentaţie parenterală, cateterizări vasculare etc.) (1). Germenii cei mai implicaţi în producerea infecţiilor neonatale în maternităţile din România sunt germenii gram ne-

gativi (*E. coli, Klebsiella, Enterobacter* etc.) iar dintre gram pozitivi *S. aureus* şi mai rar stereptococul beta hemolitic de grup B care este predominant în infecţiile nou-născutului în SUA.

OBIECTIVE

Identificarea factorilor de risc cu rol în producerea infecţiilor materno-fetale şi nosocomiale în secţii de nou-născuţi de nivele diferite din două maternităţi din România : Spitalului Clinic de Obstetrică Ginecologie „Buna Vestire" Galaţi (Lot A) şi Spitalului Clinic de Obstetrică Ginecologie „Cuza-Vodă" Iaşi (Lot B).

MATERIAL ŞI METODĂ

Studiu retrospectiv şi prospectiv pe o perioadă de 4 ani în două maternităţi de nivele diferite din regiunea Moldovei, nivel II – lot A şi nivel III – lot B, în secţiile de nou-născuţi.

Secţiile de nivel II şi III au fost definite conform OM 910/2001 secţiile de nivel II îngrijesc nou-născuţi normali în special şi nou-născuţi prematuri peste 34 săptămâni de gestaţie cu patologie uşoară, iar secţiile de nivel III îngrijesc toată patologia neonatală severă şi nou-născuţi normali.

În perioada analizată (2006 – 2009) în Spitalului Clinic de Obstetrică Ginecologie „Buna Vestire" Galaţi din numărul total de nou-născuţi (4267 nou-născuţi) 381 au prezentat infecţii neonatale, aceştia reprezentând lotul A de studiu. În aceeaşi perioadă în Spitalul Clinic de Obstetrică Ginecologie „Cuza-Vodă" Iaşi din numărul total de nou-născuţi (28112 nou-născuţi) 2791 au prezentat infecţii neonatale (Lot B).

Au fost luate în studiu : incidenţa infecţiilor pe grupe de vârstă (prematuri şi nou-născuţi la termen) ; factorii de risc în producerea infecţiei : colonizare maternă, colonizarea neonatală, colonizarea personalului medical pe tipuri de germeni ; identificarea germenilor în testele de sanitaţie ; corelarea colonizării materne cu colonizarea nou-născutului şi infecţia nou-născutului ; corelarea colonizării personalului cu colonizarea nou-născutului şi infecţia nou-născutului ; corelarea normelor de igienă cu colonizarea nou-născutului şi infecţia nou-născutului ; identificarea germenilor la mama, la personalul medical şi prin testele de sanitaţie a fost făcută aleatoriu. Prelucrarea statistică a datelor a fost realizată în SPSS 16, prin teste parametrice şi neparametrice specifice tipului de date, evaluarea rezultatelor făcându-se pe baza indicatorilor statistici descriptivi.

REZULTATE ŞI DISCUŢII

Incidenţa colonizării şi infecţiei la nou-născut în perioada studiată

În perioada 2006 –2009 din numărul total de 4267 nou-născuţi din Spitalului Clinic de Obstetrică Ginecologie „Buna Vestire" Galaţi, 804 cazuri au prezentat colonizări bacteriene iar infecţii materno-fetale şi nosocomiale au fost identificate la 381 nou-născuţi reprezentând 8.93% din numărul total de naşteri în perioada studiată. În lotul B de studiu (Spitalului Clinic de Obstetrică Ginecologie „Cuza-Vodă" Iaşi) din numărul total de naşteri (28112 naşteri, în perioada 2006-2009) s-au înregistrat 5504 cazuri cu colonizări din care 2791 nou-născuţi au prezentat infecţii (9.93%).

Studiul evidenţiază faptul că incidenţa prezenţei germenilor a fost semnificativ mai mare ($p=0.017$, $\chi^2=5.65$, 95%CI) în Spitalului Clinic de Obstetrică Ginecologie „Cuza-Vodă" Iaşi – (Nivel III 19.58% versus 18.84% Nivel II), datorită faptului că în Spitalului Clinic de Obstetrică Ginecologie „Cuza-Vodă" Iaşi funcţionează Centru Regional de Terapie Intensivă care îngrijeşte nou-născuţi proveniţi prin transfer din regiunea Moldovei, nou-născuţi din cadrul maternităţii şi prematuri, însă rata de infecţie între cele două maternităţi nu prezintă diferenţă semnificativă aspect ce poate fi explicat prin

TABELUL I
Factorii de risc implicaţi în apariţia infecţiei neonatale

faptul că procedurile de îngrijire efectuate după protocoale bine puse la punct sunt net superioare fată de nivelul II de secţie unde nu există protocoale de practică.

Factorii de risc implicaţi în colonizarea şi infecţia nou-născutului

În lotul A incidenţa nou-născuţilor prematuri cu infecţie neonatală este semnificativ mai mică (1,48%) comparativ cu lotul B (6,7%). O diferenţă semnificativă între cele două loturi a fost înregistrată de asemenea pentru incidenţă nou-născuţilor cu infecţie şi vârste de gestaţie peste 37 săptămâni, în lotul A aceasta fiind semnificativ mai mare (3,02%) comparativ cu lotul B (0,03%), aceste rezultate pot fi explicate prin faptul că secţia de nivel II conform ordinului 910/2001 nu are competenţe de a îngriji nou-născut cu vârste de gestaţie sub 34 săptămâni. Analiza corelaţională a demonstrat existenţa unei asocieri semnificative între VG şi prezenţa infecţiilor neonatale, acestea fiind frecvente la vârste de gestaţie mici ($r=-0.82$, $p=0.0003$, 95%CI).

Colonizarea maternă - germeni izolat la mamă în urocultură şi lohicultură.

Cazurile selecţionate în lotul studiat au fost diferenţiate în funcţie de tipul de germene, frecvenţa a fost calculată raportându-ne la numărul anual de naşteri. Din analiză reiese faptul că germenii frecvent izolaţi la mama atât în lohicultură cât şi în urocultură au fost gram negativii, aspect regăsit în ambele secţii (secţia de nivel II - 22.2%, secţie de nivel III – 19.21%). Germenii gram pozitivi au prezentat o frecvenţă redusă în ambele loturi de studiu (5.09% - lot A vs. 7.1% lot B).

Cel mai frecvent germen izolat la mama a fost *Escherichia coli* atât pentru Spitalului Clinic de Obstetrică Ginecologie „Buna Vestire" Galaţi (16.12%) cât şi pentru Spitalului Clinic de Obstetrică Ginecologie „Cuza-Vodă" Iaşi (12.69%). Colonizarea maternă vaginală sau urinară cu *E.coli* îşi are explicaţia în igiena precară a gravidei şi lehuzei. În secţiile de nivel III o frecvenţă mai mare comparativ cu cele de nivel II a fost semnalată pentru streptococul beta hemolitic de grup D (2.91% nivel III vs. 2.64% nivel

II), *S. aureus* (2.03% nivel III vs. 1.33% nivel II), *Klebsiella pn.* (1.84% nivel III vs. 1.62% nivel II) *Enterococcus* (1.66% nivel III vs. 1.42% nivel II). Frecvenţe de sub 1% au fost înregistrate pentru *Str. agalactiae, Pn. aeruginosa, s*tafilococ coagulazo negativ, Proteus (0.09% nivel III vs. 0.02% nivel II), *Str. viridans* (0.02% - nivel III vs. 0% nivel II), *Acinetobacter spp*. (0.01% nivel III vs. 0.05% nivel II), *Citrobacter spp*. (0.01% - nivel III vs. 0.03% nivel II) şi SBHB (0.02% atât în secţiile de nivel II cât şi în secţiile de nivel III).

Tipul de germen izolat la nou-născut

Analiza tipurilor de germeni la nou-născut a demonstrat faptul că în secţia de nivel II (Lot A) frecvenţa maximă a fost înregistrată pentru *Escherichia coli* (4.98%) fiind urmată de *S. aureus* (3.69%) şi stafilococ coagulazo negativ (1,47%). Valorile frecvenţei întâlnite în aceste secţii sunt semnificativ mai mici faţă de frecvenţele întâlnite în secţiile de nivel III în care *Escherichia coli a* fost identificată la 5.97%, pentru *S. aureus* la 4.76% iar în cazul stafilococului coagulazo-negativ s-a înregistrat o frecvenţă dublă a colonizărilor nou-născuţilor (2.46%). O situaţie diferită este întâlnită în cazul colonizării cu *Klebsiella* şi *Enterobacter* pentru care frecvenţa nou-născuţilor este mai mare în cazul celor proveniţi din secţiile de nivel II (2.97% vs. 1.73% - *Enterobacter* şi 2.87% vs. 2.43% - *Klebsiella pn.*). În secţiile de nivel II o frecvenţa scăzută dar semnificativ mai mare faţă de secţiile de nivel III a fost întâlnită pentru *Enterococcus* (1.12% vs. 0.5%) şi *Citrobacter* (0.5% vs. 0.15%). Colonizarea cu *Ps. aeruginosa*, *Acinetobacter spp.*, *Str. virindas*, streptococ beta hemolitic de grup B (SBHB), *Str. agalactiae* a prezentat o frecvenţă mai mică cu diferenţe mici între cele două spitale (nivel II vs. nivel III).

Cel mai puţin frecvent izolat germen la nou-născut a fost streptococul beta hemolitic de grup B 0.11% în timp ce în ţări ca şi SUA 2% din nou-născuţi pot fi colonizaţi cu streptococ beta hemolitic care ulterior poate să inducă pneumonie congenitală sau septicemie (4, 5).

Rata de infecţie la nou-născuţi

Analiza s-a făcut în funcţie de debutul semnelor clinice de infecţie (sub 72 ore şi peste 72 ore) conform definiţiei infecţiei materno-fetale şi nosocomiale date de CDC. În lotul A semnele clinice de infecţie care au debutat în primele 72ore postnatal au fost în procent de 1.85% (din numărul total de naşteri), cele ce au apărut după 72 de ore au fost de 8.91% (infecţie nosocomială. În lotul B incidenţa infecţiilor nosocomiale înregistrează o valoare mai mică 7.46%.

Cele mai frecvente infecţii la nou-născut au fost cele localizate (8.8%), iar septicemia a prezentat o incidenţă mai mică însă ce diferă semnificativ ($\chi^2=5.81$, $p=0.0159$) între cele două loturi analizate (1.95% - lot A vs. 1.41 – lot B).

În secţiile de nivel II cel mai frecvent germen izolat a fost *E.coli* (3.85%) urmând apoi *Klebsiella pn*. (1.57%) şi *Enterobacter* (1.24%). În secţiile de nivel III la nou-născuţii infectaţi s-a izolat frecvent aceeaşi germeni : *E. coli* (3.7%), *S. Aureus* (2.15%), *Klebsiella pn*. (1.22%) şi *Enterobacter* (0.98%).

Contaminarea mediului de spital

În maternitatea Spitalului Clinic de Obstetrică Ginecologie „Buna Vestire" Galaţi nu există o rutină în supravegherea mediului de spital, numărul probelor fiind foarte mic în raport cu cele recoltate în lotul B, rezultatele studiului comparativ între cele două maternităţi din acest punct de vedere are o acurateţe scăzută.

În lotul A din totalul probelor recoltate în perioada 2006-2009 (512), 32 (6.25%) au fost pozitive, acestea determinând apariţia infecţiei neonatale la 1.73% nou-născuţi (tab. I).

În lotul B contaminarea mediului de spital a fost investigat prin recoltări periodice,

astfel din totalul probelor recoltate în Spitalul Clinic de Obstetrică Ginecologie „Cuza-Vodă" Iaşi (nivel III) în perioada 2006-2009 (5512), 64 (1.16%) au fost pozitive, cauzând infecţie neonatală la 0.45% nou-născuţi, pondere semnificativ mai mică comparativ cu valoarea înregistrată în lotul A de studiu (1.73%), aspect ce demonstrează riscul crescut de infecţie neonatală în secţiei de nivel II (tab. I).

În lotul A (nivel II) riscul de infecţie neonatală datorat contaminării suprafeţelor (RR=1.77) este semnificativ mai mare comparativ cu riscul existent în secţia de nivel III (lot B) (RR=0.2).

Colonizarea personalului medical

Germenul cel mai frecvent implicat în colonizarea personalului medical a fost *S. aureus*. Studiul evaluează frecvenţa colonizării personalului cu Stafilococ auriu meticilinorezistent (MRSA) şi stafilococ auriu oxacilinosensibil (OSSA) atât în lotul A cât şi în lotul B.

În perioada analizată (2006 – 2009) în Spitalului Clinic de Obstetrică Ginecologie „Buna Vestire" Galaţi s-au analizat 974 probe de exsudat nazal ale personalului, dintre aceste 211 probe au evidenţiat prezenţa *S. aureus* (21.66%) afectând 177 nou-născuţi (94 -2.2% colonizaţi şi 83-1.95% infectaţii neonatale). În lotul B din 3992 probe exsudat nazal recoltate, din care 684 s-au pozitivat (17.13%). Se remarcă faptul că în secţia de nivel II colonizarea personalului reprezintă o incidenţă mai mare (21.66% vs. 17.13%) (tab. I).

În secţia de nivel II rezultatele demonstrează existenţa unei corelaţii moderate (r=0.63, p=0.0357) între colonizarea personalului şi infecţia neonatală, aceasta nereprezentând un factor de risc major în apariţia infecţiilor la nou-născut (RR, OR=0.94). În secţia de nivel III analizată riscul de apariţie a infecţiei la nou-născut datorate colonizării personalului este nesemnificativ (OR=0.6, χ^2=15.287, p=0.02045, RR=0.7, r=0.51, p=0.041 (tab. I). Comparând valorile raportului de risc şi gradul de asociere al colonizării personalului cu infecţia neonatală se constată faptul că colonizarea personalului nu reprezintă un risc major de apariţie a infecţiilor neonatale însă se poate aprecia faptul că în lotul A de studiu (secţie de nivel II) riscul a fost mai ridicat (RR=0.94) comparativ cu cel întâlnit în lotul B (RR=0.7).

Analiza lotului A a demonstrat existenţa unei corelaţii semnificative între tipul de germene identificat la mamă şi tipul de germene identificat la nou-născutul cu infecţie. (r=0.5587, p=0.001342). În lotul B de studiu corelaţia între tipul de germene identificat la mamă şi tipul de germene identificat la nou-născutul cu infecţie este semnificativă (r=0.75, p=0.0000327, 95%CI).

Comparând gradul de asociere dintre tipul de germene identificat la mamă şi cel identificat la nou-născut în cele două loturi studiate, rezultă faptul că în secţiile de nivel II corelaţia este mai mică (r=0.558, p=0.0013) comparativ cu corelaţia întâlnită în secţiile de nivel III (r=0.755, p=0.00003), aspect ce poate fi explicat prin faptul că în secţiile de nivel II infecţia nou-născutului poate fi determinată şi de alţi factori în afara colonizării materne.

În secţiile de nivel III principalul factor ce influenţează apariţia infecţiei la nou-născut este colonizarea maternă, restul factorilor de risc fiind implicaţi mai puţin. În secţiile de nivel II doar 1/4 din nou-născuţii ce prezintă germeni gram pozitivi provin din mame colonizate cu germeni din acelaşi grup în timp ce în secţiile de nivel III mai mult de jumătate dintre nou-născuţii colonizaţi cu germeni din acest grup provin din mame colonizate cu germeni de acelaşi tip.

Analiza transmiterii germenilor de la mama la nou-născut în cele două maternităţi de nivele diferite evidenţiază aspecte diferite. Acestea constau în faptul că în secţiile de nivel III (Iaşi) din mamele cu infecţii

(15.1% Galaţi, 11.2% Iaşi) deşi avem o colonizare mai mare a nou-născutului (nou-născuţi colonizaţi 5.5% Galaţi vs. 7% Iaşi) frecvenţa infecţiilor la nou-născut (1.41% -Iaşi) este semnificativ mai mică în secţia de nivel III comparativ cu secţiile de nivel II (2.06%-Galaţi), aspect explicat prin procedurile de îngrijire (fig.10).

O situaţie diferită este semnalată în cazul nou-născuţilor cu infecţii ce provin din mame colonizate, pentru aceştia înregistrându-se o frecvenţă semnificativ mai mare în secţia de nivel III – Iaşi (7.04%) comparativ cu secţia de nivel II – Galaţi (5.25%), aspect ce poate fi explicat şi prin faptul că aceşti nou-născuţi prezintă o patologie asociată complexă ce creşte semnificativ riscul pentru infecţie (tab. I).

Analiza riscului pe care colonizarea mamei o prezintă pentru infecţia neonatală a fost evaluată realizând tabelele de contingenţă ce priveşte frecvenţa infecţiei în raport cu numărul total de naşteri în perioada studiată.

În secţiile de nivel II (lot A) riscul de apariţie a infecţiei la nou-născut în cazul colonizării materne a fost de 8.64 ori mai mare (RR=8.64, p<<0.05). Există o corelaţie semnificativă între colonizarea maternă şi prezenţa infecţiei la nou-născut (r=0.87, p<<0.05, 95%CI). În secţiile de nivel III riscul de apariţie a infecţiei la nou-născut datorate colonizării materne a fost de 13.32 ori mai mare (RR=13.32, p<<0.05, 95% CI, (r=0.91, p<<0.05) (tab. I).

Comparând rezultatele se remarcă faptul că în secţiile de nivel III riscul apariţiei infecţiei la nou-născut datorate colonizării materne este semnificativ mai mare (RR= 13.32) faţă de riscul apariţie a infecţiei neonatale în secţiile de nivel II (RR=8.64) aspect justificat prin faptul că în producerea infecţilor intervine şi factorul gazdă.

CONCLUZII

Incidenţa infecţiilor în cele două maternităţi a fost de 1.85% infecţii materno-fetale în lotul A şi 2.75% în lotul B iar a infecţiilor nosocomiale a fost de 8.91% în lotul A şi 7.46% în lotul B.

Factorii de risc implicaţi în infecţia nou-născutului a fost prematuritatea (RR=12.9 -lot A, RR=58.2-lot B), colonizarea maternă (RR=8.6-lot A, 13.3-lot B), colonizările nazale ale personalului medical (RR= 0.94–lot A, RR=0.7–lot B) şi într-o mică măsură mediul de îngrijire (RR=1.7–lot A, RR=0.2–lot B).

Germenii cel mai frecvent implicaţi atât în colonizarea şi infecţia maternă cât şi în colonizarea şi infecţia nou-născutului au fost gram negativii (E.*coli, Klebsiella pn. Enterobacter, Entorococcus*) şi *S.aureus* meticilino reziztent (MRSA).

Există o corelare semnificativ statistică între colonizarea maternă şi colonizarea/ infecţia nou-născutului (r=0.8-lot A, r= 0.9-lot B) şi de asemnea o corelarea între colonizarea personalului medical (*S.aureus*) şi infecţia neonatală (r=0.6-lot A, r=0.5 -lot B).

Cele mai frecvente infecţii ale nou-născutului au fost cele localizate (8.81%-lot A, 8.8%-lot B) iar septicemia a reprezentat 1.9% din nn lotului A şi 1.4% din nn lotului B.

Există diferenţe semnificative intre colonizările şi infecţiile nou-născutului între cele două maternităţi aspect ce poate fi explicat prin faptul că în secţia de nivel III procedurile de îngrijire sunt efectuate după protocoale foarte bine puse la punct acestea fiind net superioare fată de nivelul II de secţie unde încă nu există protocoale de practică.

NOUTĂŢI

EFICIENŢA ASOCIERII AMOXICILINĂ - METRONIDAZOL ÎN ÎNGRIJIREA PARODONTITELOR AGRESIVE GENERALIZATE

Studiul realizat de un grup de cercetători parodontologi din cadrul Universităţii din Istanbul a avut ca scop evaluarea efectelor combinaţiei metronidazol-amoxicilină asupra parametrilor clinici şi microbiologici la pacienţii diagnosticaţi cu parodontită agresivă generalizată. În studiu au fost incluşi douăzeci şi opt de pacienţi, repartizaţi în 2 loturi : lotul de studiu (n = 12) şi lotul martor (n = 16). Lotul de studiu a primit asocierea amoxicilină-metronidazol alături de detartraj şi planare radiculară. Lotul martor a primit doar detartraj si planare radiculară. Alături de examenul clinic, au fost analizate probe de placă subgingivală pentru bacterii total cultivabile şi prezenţa de *Porphyromonas gingivalis*, *Tannerella forsythia* (anterior *T. forsythensis*), *Treponema denticola*, *Prevotella intermedia*, *Prevotella nigrescens*, *Prevotella pallens*, şi *Aggregatibacter actinomycetemcomitans* (anterior *Actinobacillus actinomycetemcomitans*) folosind reacţia în lanţ a polimerazei (PCR). Rezultatele studiului indică faptul că la ambele loturi, toţi parametrii clinici au fost îmbunătăţiţi semnificativ comparativ cu valorile iniţiale ($P < 0,05$). A existat o reducere semnificativă statistic a profunzimii pungii parodontale şi s-a obţinut un câştig de ataşament la lotul de studiu comparativ cu lotul martor ($P < 0,05$). Numărul total de bacterii, a scăzut în mod semnificativ la 3 şi 6 luni la ambele loturi ($P < 0,05$). *T. denticola* şi *T. forsythia* au fost bacteriile cel mai des întâlnite pe parcursul studiului. *T. denticola* a arătat o scădere continuă de peste 6 luni la lotul de studiu, în timp ce la lotul martor nu a fost observată nici o schimbare după 3 luni. *P. gingivalis* a scăzut în mod semnificativ la 3 luni ($P < 0,05$), în timp ce *T. forsythia* a fost singurul patogen care a fost scăzut sub limitele de detecţie, de terapia asociată, cu o diferenţă semnificativă ($P < 0,05$) comparativ cu lotul martor. Rezultatele acestui studiu arată că asociaţia amoxicilină - metronidazol utilizată ca adjuvant la detartraj şi planare radiculară conduce la o vindecare clinică mai bună comparativ cu tratamentul mecanic singur. Terapia medicamentoasă folosită a avut ca rezultat o scădere semnificativă şi substanţială a *T.forsythia* şi a prevenit recolonizarea sa timp de 6 luni, sugerând astfel faptul că *T.forsythia* poate determina stabilitatea pe termen lung a rezultatelor tratamentului parodontal (Yek EC, Cintan S, Topcuoglu N, Kulekci G, Issever H, Kantarci A. Efficacy of amoxicillin and metronidazole combination for the management of generalized aggressive periodontitis. *J Periodontol* 2010 ; 81 (7) : 964-974).

PRIMARY GASTRIC LYMPHOMA IN A PROSPECTIVE STUDY (Abstract). **Aim**: To assess the of occurrence of primary gastric lymphoma using epidemiological, clinical and biological data. This rare pathology includes more different histological subtypes that can affect different segments of gastrointestinal tract. **Material and methods**: Retrospective analysis of the hospital-based medical records of patients with primary gastrointestinal lymphoma admitted in the Hematology Clinic of the University Emergency Hospital of Bucharest between October 2014 and June 2018. The analyzed data included demographic data, *Helicobacter pylori* infection, disease staging, laboratory tests and objective examination. All the patients made a CT scan of the chest, abdomen and pelvis. The histological diagnosis was based on biopsy specimens in performing upper digestive endoscopy and immunohistochemistry. All data was statistically analyzed using *STATA 13* (Stata Corp LLC US). **Results**: This study included 21 patients that have been diagnosed with primary gastrointestinal lymphoma. It was observed that primary gastric lymphoma frequently affects more females than males. Histopathological, the majority of primary gastric lymphoma (90.41%) were B-cell lineage and diffuse large B-cell occurred in 66.66% of cases. Out of the 21 patients surveyed, 13 (61.90%) presented loss of appetite, 9 (42.85%) had abdominal pain. Anemia was present in 16 cases. **Conclusions**: The majority cases in our study were diffuse large B-cell lymphoma which were related to infection with *Helicobacter pylori* in half the cases. **Keywords**: GASTRIC LYMPHOMA, HELICOBACTER PYLORI, MUCOSA-ASSOCIATED LYMPHOID TISSUE LYMPHOMA, DIFFUSE LARGE B-CELL LYMPHOMA.

In the last years, the incidence of gastrointestinal lymphoma is rising. This rare pathology includes more different histological subtypes that can affect different segments of gastrointestinal tract (1, 2). The stomach is frequently affected by two subtypes of lymphoma and is related with chronic inflammation made by *Helicobacter pylori* infection (3).

Chronic inflammation leads to a hyperstimulation of T helper lymphocytes, which in turn stimulates the proliferation of B-lymphocytes from the gastric mucosa with mutations and subsequent transformation

into gastric lymphoma (4,5). Gastric MALT (mucosa-associated lymphoid tissue) lymphoma has a higher survival rate that can reach 90% at ten years because is an indolent disease (6). Are cases that can develop from MALT lymphoma in Diffuse large B-cell lymphoma (DLBCL) with an unfavorable prognosis, survival rate dropping until 42% (6). Some substances, such as fungicides, pesticides, solvents, were related to a higher incidence of lymphoma (7) and current screening test are not sensitive enough for early detection of the risk, as also seen for other occupational induced diseases (8).

Taking into consideration these aspects, **the aim** of this study is to assess the occurrence of primary gastric lymphoma using epidemiological, clinical and biological data.

MATERIAL AND METHODS

Population. Variables

In this study were evaluated 51 patients diagnosed with primary gastrointestinal lymphoma, admitted in the Hematology Clinic of the University Emergency Hospital of Bucharest, between October 2014-June 2018. All patients included in the study signed and agreed the participation in the research process before any maneuvers (9, 10).

From those 51 patients, was selected a number of 21 (41.17%) patients that have been diagnosed with primary gastric lymphoma with different histological subtype. All of those patients performed upper digestive endoscopy with biopsy sampling for testing *Helicobacter pylori*. All patient with secondary gastric lymphoma were excluded from our analysis.

Variables analyzed included demographic data, the presence of symptomatology B (fever, weight loss without trying, exceeding 10% of body weight in 6 months, and profuse sweating), histological subtype, *Helicobacter pylori* infection, disease staging, performance status, lactate dehydrogenase (LDH), and the International Prognostic Index (IPI).

For the observed patients, examination included also the presence of general signs, assessment of peripheral adenopathies, hepatosplenomegaly, assessment of the general status of the patient in order to calculate the performance status (ECOG). Laboratory analyzes included complete blood count, transaminases, serum lactate dehydrogenase, albumin, immunoelectrophoresis, uric acid, coagulogram, viral serology such as hepatitis C virus (HCV), Human Immunodeficiency Virus (HIV) and Epstein Barr virus (EBV), antibodies of *Helicobacter pylori*.

The histological diagnosis was based on the biopsy specimens obtained during the upper digestive endoscopy and immunohistochemistry. The histological classification was performed according to the World Health Organization classification (2016) and staging was based on the Ann Arbor modified Musshoff classification (11, 12). Also, it was performed bone marrow aspirate with a biopsy. All the patients performed a CT scan of the chest, abdomen and pelvis. Histological remission according to *Groupe d' Etude des Lymphomes de l'Adulte* (GELA) criteria include the necessity for endoscopic biopsy follow-up (13).

Analysis method

The statistical analysis was performed using STATA 13 software. In order to estimate the survival probability from observed survival times, the Kaplan-Meier (KM) method

is used (14). The survival probability at time t_i, $S(t_i)$ is calculated as follow:

$S(t_i)=S(t_{i-1})(1-(d_i/n_i))$

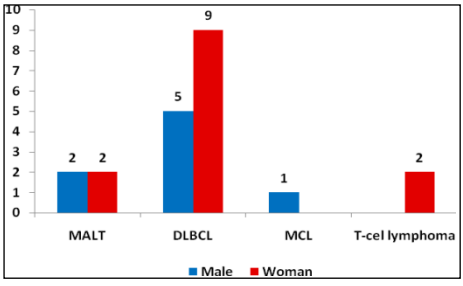
where,

- $S(t_{i-1})$ is the probability of being alive at t_{i-1}
- n_i is the number of patients alive just before t_i
- d_i is the number of events at t_i
- $t_0 = 0$, $S(0) = 1$

The estimated probability $(S(t))$ is a step function that changes value only at the time of each event. It's also possible to compute confidence intervals for the survival probability. The KM survival curve, a plot of the KM survival probability against time, provides a useful summary of the data that can be used to estimate measures such as median survival time.

RESULTS

Gender distribution depending on histological subtype is presented in first figure. From this graphic it can be observed that females were more frequently affected than males. Histopathological, the majority of primary gastric lymphoma (90.41%) were B-cell lineage and diffuse large B-cell occurred in 66.66% of cases. In study group, 47.62% were smokers.



*MCL= Mantle Cell Lymphoma

Fig. 1. Types of gastric lymphoma distribution, by gender

The results obtained by using survival analysis are presented in first table. The results (tab. I) show that, the most frequent symptom was loss of appetite in 13 (61.90%) patients and abdominal pain in 9 (42.85%) patients. LDH was elevated in 80.95% of the cases. Hypoalbuminemia was found in 85.71% of patients. Bleeding at presentation was present in 5 patients and anemia was only present in 16 cases. Localized disease (Ann Arbor stages I or II) was present in 7 (33.34%) of cases and the rest were advanced stages (III-IV). From our study 11 (52.38%) patients died, 9 (42.85%) of them were diagnosed with DLBCL, all with III-IV stage Ann Arbor, high IPI score and ECOG ≥2. All patients were tested for infection with *Helicobacter pylori* using antibodies and biopsy sampling that were positive for 7 patients and respectively 10 patients. Treatment was different for each patient, 5 patients diagnosed with DLBCL and 2 patients with T-cell lymphoma suffered emergent surgery. Patients tested positive for *Helicobacter pylori* received eradication therapy. Chemotherapy regimens consisted in administration of 6-8 application of R-CHOP (rituximab-cyclophosphamide, doxorubicin, vincristine and prednison) for MALT, DLBCL and MCL and for T-cell lymphoma was administered R-COEP (rituximab-cyclophosphamide, epirubicin, vincristine and prednisone). The only case with MCL was without response to 8 application of R-CHOP regimens and received Ibrutinib 560 mg per day obtaining complete remission. We have 50 months of surveillance and approximately 30% of patients are alive, no statistical differences are noted for MALT and DLBCL (fig. 2).

TABLE I

Baseline characteristics of primary gastric lymphoma patients and their significance level

Parameters	MALT	DLBCL	MCL	T-cell lymphoma	Total number of patients	p-value
Age ≥ 60 years	2 (9.52%)	12 (57.14%)	1 (4.76%)	1 (4.76%)	16 (76.19%)	0.046 (S)
Elevated LDH	1 (4.76%)	14 (66.6%)	1 (4.76%)	1 (4.76%)	17 (80.95%)	0.045 (S)

Death	1 (4.76%)	9 (42.85%)		1 (4.76%)	11 (52.38%)	0.257 (NS)

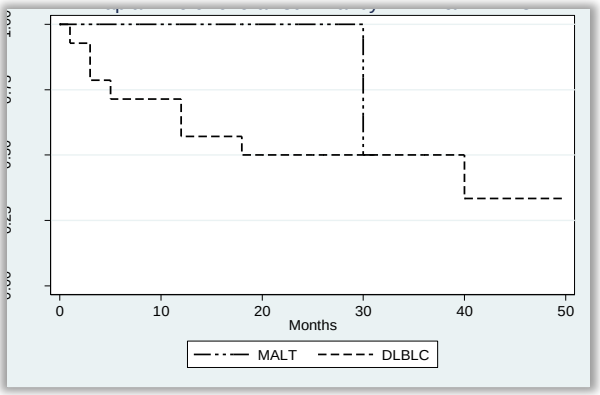

Fig. 2. Kaplan-Meier survival curves for MALT and DLBCL.

DISCUSSION

The results obtained from the data analysis answered to the research objective established. We assumed that in gastric MALT lymphoma is difficult to establish the diagnosis due to normal endoscopy findings in many cases. In our analysis were used 51 patients which were diag-

nosed with primary gastrointestinal lymphoma, admitted in the Hematology Clinic of the University Emergency Hospital of Bucharest. The stomach represents the most common site of gastrointestinal tract affected by lymphoma due the fact that chronic inflammation is caused often by the infection with *Helicobacter pylori*.

Our study shows that, the majority of the patients were females and that a chronic inflammation pathology is hard to diagnose, most cases being diagnosed in late stages, as demonstrated (66.64% cases - stages III-IV Ann Arbor) due to indolent evolution, poor clinical picture, most clinical manifestations occurring late in the disease.

In gastric MALT lymphoma is difficult to establish the diagnosis due to normal endoscopy findings in many cases. Ideally, all patients should benefit from superior digestive endoscopy for biopsy harvesting, even if the mucosa is absolutely normal. Since endoscopic techniques have advanced in recent years, endoscopy can improve treatment strategies. It is also important that biopsy specimens to be examined by anatomo-pathologists in the field for early diagnosis and survival of this patient population.

For histological diagnosis to be correct, about 10-20 biopsies from several regions of the stomach should be obtained (15, 16). For those cases receiving primary surgery for digestive hemorrhages that cannot be managed endoscopically, careful histopathological examination is recommended.

Another endoscopic tool that can be easily used in the staging of this pathology is echoendoscope, which can appreciate the degree of infiltration of the gastric wall, extramural dissemination, and lymph node damage (17).

Besides, the gastro-intestinal site extranodal MALT lymphoma the most frequent sites of infiltration are the salivary glands, lung and thyroid (6) and a differential diagnosis has to be done with primary tumors with this localization (18) in order to achieve this objective. Being meticulous on the patient examination and on the following treatment we can stage the disease and prevent the transforming into DLBCL forms (6). In our country with increased prevalence of tuberculosis (19), the combination of multiple risk factors (20, 21) may increase the risk of hospitalization of these patients and implicitly the incidence of hospital infections (22), especially in patients with comorbidities (23) with associated cardiovascular diseases (24, 25, 26) that may associate gastric lymphoma and other types of cancers (27, 28, 29, 30).

In our study, primary gastric lymphoma affects older females and the common complaints were loss of appetite, abdominal pain and anemia secondary to blood loss. The majority of studies in this domain reflected that this pathology is frequent to males (31).

Recent meta-analyzes have shown that smoking is considered a risk factor for patients diagnosed with gastric cancer, thus counseling for smoking cessation being very important (32, 33). The association between smoking and gastric lymphoma needs to be studied more carefully considering that most patients are smokers (34, 35, 36).

LDH is an important prognostic factor. Although specialty studies did not support hypoalbuminemia as a prognostic factor, it should be taken into consideration because most of our patients (85.71%) experienced hypoalbuminemia. To demonstrate this, additional studies that include a larger number of patients are needed.

In the 50-month period, rate of survival

of for the patients diagnosed with gastric lymphoma, the MALT lymphoma survival was superior to those with DLBCL, with 100% of the former with a survival of up to 30 months, only 75% of those with DLBCL had a survival of 6 months, about 60% had a survival of 10-18 months and only 50% had a survival of 19-40 months. A 30% of those with DLBCL gastric lymphoma showed a survival of 40-50 months.

Most of those lymphomas were present in patients with age ≥ 60 years, diagnosed in advanced stages of the disease and having high mortality.

CONCLUSIONS

In our study we highlighted that the primary gastric lymphomas are a rare pathology, difficult to diagnose, especially because clinical manifestations are unspecific and endoscopic appearance is not typical. In this paper the majority cases of primary gastric lymphoma were diffuse large B-cell lymphoma which were related to infection with *Helicobacter pylori* in half of the cases.

DIFFERENTIATION OF PATIENTS WITH CHRONIC LOMBOSCIATICA DUE TO DISC HERNIA USING GAIT ANALYSIS TECHNIQUES (Abstract): Nowadays gait analysis represent a modern technique used as a useful tool in the assessment of patients with locomotors disease. **Aim**: To make a differentiation of patients with chronic sciatica due to disc hernia using gait analysis techniques. **Material and method**: Study was prospective, with consecutive selection of subjects according to eligibility criteria, using a control group. The number of subjects was 47: 28 patients and 19 healthy subjects. The patients were characterized clinically, imagistically and biomechanically. The biomechanically evaluation was made with VICON MX optical motion capture system. Our data of interest were: temporo-spatial and kinematic parameters. These data were factorial analyzed with a principal component extraction technique, resulting 10 variables, which characterized the system variability in 94.67%. Next step was represented by a hierarchical cluster analysis for sub-group identification. **Results**: We have differentiated two clusters. The two clusters were individualized regarding the temporo-spatial parameters (opposite foot contact, step width) as well as the kinematic parameters (maximum upward rotation in stance of pelvis, maximum adduction of the hip in stance, maximum abduction of the hip in swing, maximum plantar flexion angle in swing, total sagittal plane excursion of the ankle). **Conclusions**: The two clusters can be defined as following: cluster 1: reduced stance phase and mainly distal problems (of the ankle); cluster 2: normal stance phase duration, severely low step width and mainly proximal problems (pelvic belt). **Key words**: GAIT PATTERN, CLUSTER, SCIATICA

A series of previous studies centered on gait analysis, which have focused both on healthy patients (1,2) and on patients with different musculo-skeletal conditions (3) provided a large amount of data of high interest for the improvement of rehabilitation programmes.

Our study focused on patients with chronic lombosciatica due to disc hernia and was motivated by the prevalence of this pathological type which is constantly increasing within general population (4,5,6,7) as well as by the severe socio-economical impact it generates (8,9).

The results of the study will help improving or creating rehabilitation programmes, making them more appropriate for the case.

AIM OF THE STUDY

The aim of our study was to make a differentiation of patients with chronic sciatica due to disc hernia using gait analysis techniques

MATERIALS AND METHOD

STUDY DESIGN

Study was prospective, with consecutive selection of patients according to inclusion and exclusion criteria, using a control group.

Inclusion criteria were : age above 18, mechanical low back pain unilaterally irradiated on radicular territory of L5/S1 ± neurological signs corresponding to the radicular affection (without motor deficit), chronic clinical phenomena with a duration of at least 4 weeks, presence of lumbar disc hernia documented through CT or MRI, patients with independent walking ability. Exclusion criteria were : no systemic disease with relevant influence on walking ability, no orthopedic surgeries on lower limbs, conditions included in "red flags" screening, motor deficit corresponding to radicular involvement L5/S1, counter indications in CT or MRI exploring, presence of the inflammatory biological syndrome.

The number of subjects was 47 : 28 patients with chronic lombosciatica and 19 apparently healthy subjects who represent the control group. The average (± standard deviation) age, mass and height of the patients were 45 years (±12), 67.4 Kg (± 7.5), and 167.7 cm (± 7.5). The average (±standard deviation) age, mass and height of the subjects from control group were 38 years (± 8), 63.7kg (± 6.4) and 168.5cm (± 9.1).

Materials were represented by selected patient and control group, lumbar spine images (CT and IRM), patient's clinical data files and VICON MX optical motion capture system.

Method. The patients were selected and characterized clinically and imagistically. The biomechanical evaluation for patients and control group was performed with Nexus and Poligon programs. Our data of interest were : temporo-spatial parameters (opposite foot off, opposite foot contact, foot off, cadence, step length, walking speed, step time, step width, stride length, stride time) and joint angle values for pelvis, hip, knee, ankle in sagittal and/or coronal plane (fig. 1-5).

DATA ANALYSIS

There are different ways in which information may be extracted from raw data. Cluster analysis is a technique of data mining that assigns records in classes based on a similar measure. Clustering algorithms seek to fragment the entire data set into homogenous subgroups. The similarity of the data within the cluster is maximized while the similarity between the records of different clusters is minimized. As a result studying the newly created subgroups may reveal patterns that can help in defining medical features.

In our cluster analyses, the Ward's linkage method was used, with the purpose of minimizing the error sum of squares. This is related to analyses of variance ANOVA. Thus, we will find homogeneous subgroups.

OUTLIERS' DETECTION

Outliers are extreme values that may generate unstable results on the analysis. It is possible to go against the trend by using them. To eliminate the outliers we have com-

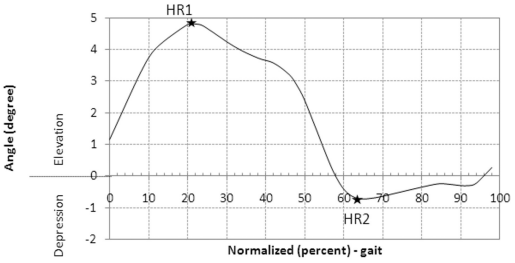

Fig. 1. Pelvis parameters (coronal plane) : HR1 : maximum upward rotation in stance, HR2 : maximum downward rotation in swing

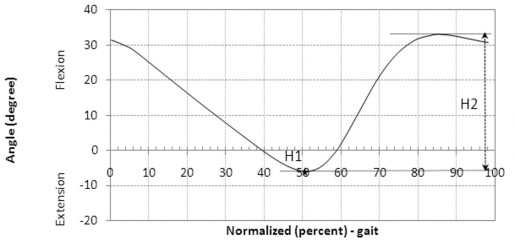

Fig. 2. Hip flexion-extension parameters (sagittal plane) H1 : maximum extension angle in stance phase, H2 : total sagittal plane excursion

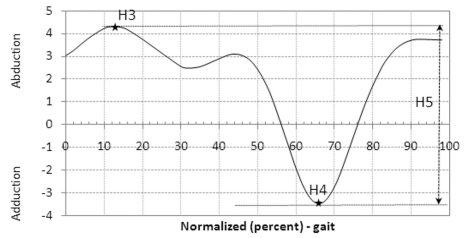

Fig. 3. Hip adduction-abduction parameters (coronal plane) H3 : maximum adduction of the hip in stance, H4 : maximum abduction in swing, H5 : total excursion of the hip

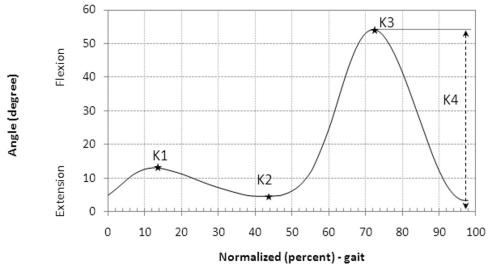

Fig. 4. Knee flexion-extension parameters (sagittal plan) K1 : maximum flexion during loading response, K2 : maximum extension in stance phase, K3 : maximum flexion in swing, K4 : total sagittal plane excursion

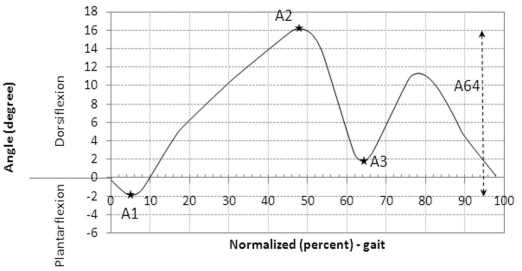

Fig. 5. Ankle dorsiflexion-plantarflexion parameters (sagittal plane) A1 : maximum plantarflexion angle during loading response, A2 : maximum dorsiflexion in stance phase, A3 : maximum plantar flexion angle in swing, A4 : total sagittal plane excursion

puted the Mahalanobis distance for every cases. Next, we have transformed these values in tailed probabilities (Chi-square distribution) and decide to eliminate those that have less than 1‰ probability. This is like the Gaussian distribution of nearly three standard deviations. It is a typical method for detecting extreme values. In our computation we did not find outliers, in fact the cases are close to less than two standard deviations equivalence.

RESULTS

All the 26 variable proposed in the study were compared between the two clusters delivered and each of them with the control group. The student (t) test was utilized and the probability $p=0.05$ was set as a level of significance.

There are the 10 variables selected by the criterion of maximum correlation with the factors derived :

- walking speed,
- maximum extension angle in stance phase of hip (H1),
- total sagittal plane excursion of ankle (A4),
- maximum dorsiflexion in stance phase of ankle (A2),
- maximum flexion angle during loading response of knee (K1),
- maximum upward rotation in stance of pelvis (HR1),
- total excursion of the hip in coronal plane (H5),
- step width, opposite foot contact,
- maximum plantarflexion angle during loading response of ankle (A1).

CHARACTERIZATION AND COMPARISON OF THE TWO CLUSTERS

We have differentiated two clusters, witch were individualized regarding the temporo--spatial parameters (opposite foot contact,

step width) as well as the kinematic parameters: maximum upward rotation in stance of pelvis (HR1), maximum adduction of the hip in stance (H3), maximum abduction of the hip in swing (H4), maximum plantar flexion angle in swing (A3), total sagital plane excursion of the ankle (A4).

RESULTS REGARDING THE TEMPORO-SPATIAL PARAMETERS

In cluster 2, opposite foot contact was achieved at the same value as in the control group. In cluster 1 this event was registered sooner (49.17+/-1.28) than in cluster 2 (50.51 +/-1.49), therefore generating a stance phase with normal duration for cluster 2, and reduced duration for cluster 1.

Both clusters patients have a lower step width compared to the control group ($p < 1‰$). In cluster 2 step, width has significantly statistical lower values than in cluster 1 ($p < 0.003$).

RESULTS FOR KINEMATIC PARAMETERS

Pelvis obliquity. The two clusters share statistically significant differences just regarding the HR1 ($p = 0.002$).

Hip kinematic parameters: the statistically significant differences between the two clusters refer only to H3 and H4

For both clusters H3 is significantly higher than in the control group ($p < 1‰$), yet in cluster 2 it has significantly statistical higher values compared to cluster 1 ($p < 1‰$).

In both clusters H4 is significantly higher than the value of control group ($p < 1‰$), but in cluster 2 the hip abduction is significantly reduced compared to cluster 1 ($p < 0.023$).

Knee. There are no statistically significant differences between the two clusters in terms of knee kinematic data.

Ankle. The two clusters show statistically significant differences in what concerns the A3 ($p < 1‰$) and A4 ($p < 0.03$). Only in cluster 1, A3 and A4 are significantly statistically different compared to

TABLE I

Mean (±standard deviation) temporo-spatial parameters divided into two clusters and control group

No.	Measure	Average +/- StDev			p - significance

the control group ($p < 1‰$). In cluster 2, these values show similarities with those in the control group.

DISCUSSIONS

The reduction of the stance phase duration in patients belonging to cluster 1 could be explained by human tendency to bring the healthy foot back on the floor more quickly (11).

Both clusters have hyperadduction in stance. Moreover, this aspect becomes more evident in cluster 2 where the adduction in stance is significantly statistically higher, compared to cluster 1. This may explain why step width is much lower in cluster 2 than in cluster 1. Other authors regarding patients with stroke (12) made the same rationality.

Hipoabduction of the hip in swing, possibly in relation with the abductor weakness, is one of the conclusions of our study which keeps within the same lines as in the literature (10).

As previous authors (10) have already exposed it, we have also noted the presence of the so called "false hip extension" which refers to a hip extension restriction during the swing phase.

A possible explanation in the occurrence of sagittal hip extension restriction is the weakness of the gluteus maximus muscle, when tonification of this muscle proves to be successful.

The pelvis changes, in coronal plane, are the results of several disturbances in links of the lower functional kinetic chain (10,13,14). HR2 is limited in the patients of both clusters and even more, there is a higher HR1 in cluster 2.

Step length and stride length are restricted in patients from both clusters compared to the control group. One explanation could be the restriction of the sagittal hip extension, which appears in all patients. Sharon Kinsella et al. (12) presented a similar reasoning.

During the initial double support, patients from both clusters show excessive ankle plantar flexion, which may be partially explained by the occurrence of a weak plantar dorsiflexor muscle eccentric contraction (15).

The swing plantar flexion is statistically significantly reduced in cluster 1, compared to cluster 2. This could be due to a weak

concentric contraction of some of the plantar flexor muscles (the long toe flexors and peroneals) (15).

CONCLUSIONS

Discussing chronic lombosciatica due to disc hernia, in terms of temporo-spatial and kinematic parameters, all patients had problems compared to the normal subjects. Only two of the temporal spatial parameters that have been discussed proved to be useful in identifying the two clusters : step width and opposite foot contact.

Several kinematic parameters have been deducted within the two clusters identification process : HR1, H3, H4, A3, and A4.

Gait characteristics are not homogenous but reveal two clusters :

Cluster 1 : reduced stance phase and mainly distal problems (of the ankle) : decreased ankle plantarflexion in swing phase and decreased total ankle excursion in sagittal plane.

Cluster 2 : normal stance phase duration, severely low step width and mainly proximal problems (pelvic belt) : hyperadduction of hip in stance phase, hypoabduction of hip in swing phase and increased pelvic upward rotation in stance.

The obtained results can be considered as useful in improving the classical rehabilitation treatment schemes applied to patients with chronic lombosciatica due to disc hernia.

In terms of rehabilitation treatment, gait examination in a modern approach, should find wider insertion in current practice.

COLPOSCOPY IN PATIENTS WITH ATYPICAL GLANDULAR CELLS ON PAP SMEARS (Abstract): The aim of this study was to review the risk of preneoplastic cervical lesions or invasive gynecologic cancer in patients with atypical glandular cells (AGC) on Papanicolaou smear and to establish the place of colposcopy in the management of these patients. **Material and methods**: We have analyzed all cases with ACG who attended our colposcopy clinic between 2001-2014. All cases were followed for a period of at least 36 months after the diagnosis of AGC on Pap smear. Medical records were reviewed to determine the clinical data, colposcopy findings and histology results. **Results:** We have analyzed 78 women with AGC on Pap smear. The age of the patients was 41+/-12.3 years old. Normal colposcopy, minor colposcopy changes, major colposcopy changes and suspicion of invasion were encountered in 44 cases (56.4%), 8 cases (10.2%), 12 cases (15.4%), and respectively, 1 case (1.3%) case. The colposcopy was not satisfactory (transformation zone type III) in 13 cases (16.6%). Histology was abnormal in 25 cases (32%) as follow: invasive cancer 5 cases (7.1%), adenocarcinoma in situ in 2 cases (2.6%), high-grade cervical lesion 8 cases (10.6%) and low-grade cervical lesion 10 cases (12.8%). **Conclusions:** The ACG diagnosis needs new strategies in order to reduce the overtreatment but not to increase the false negative results. Colposcopy is useful in cases with associated squamous cervical lesions, but new diagnostic tools are mandatory for a better management. A possible one is represented by Human Papilloma Virus test, but the place of this test should be clarified by further studies.
Keywords: ATIPYCAL GLANDULAR CELLS, HPV TESTING.

Since the introduction of well-organized screening programs, a considerable drop in the incidence and mortality of squamous cervical cancer (SCC) has been reported. The decreased incidence is achieved through detection of early abnormalities, which can be treated, avoiding the progression to invasive cancer. However, despite the screening programs for cervical cancer, in the last decades the incidence of cervical adenocarcinoma has not changed consistently (1, 2). Several studies have reported in the last two decades increasing rates of cervical adenocarcinoma relative to SCC, especially among younger women (3). This may be explained by the fact that adenocarcinomas and adenosquamos carcinomas are less amenable to prevention by screening than SCC of the cervix and cervical cytology is less sensitive and less specific for the identification of glandular neoplastic lesions of the cervix than it is for its squamous anoma-

lies (1, 4).

Because the prognosis of cervical adenocarcinoma is worse than that of squamous cervical carcinoma it is important that the disease is diagnosed as early as possible (1). The cytology plays an important role in the diagnosis and follow-up of the intraepithelial glandular lesions. However, cellular characteristics of endocervical intraepithelial precursor lesions have remained poorly documented with the exception of the adenocarcinoma in situ that has been described in detail.

The term atypical glandular cells of undetermined significance were introduced in Bethesda Nomenclature in 1989 and was defined as morphologic changes in glandular cells beyond those suggestive a benign reactive process, but insufficient for the interpretation of adenocarcinoma (5). In the 2001 Bethesda System, this category has been renamed "atypical glandular cells" (AGC), with the sub classifications "not otherwise specified" (AGC-NOS) and "favor neoplastic" (AGC-FN). The cytology report should define whether the cytological glandular abnormality relates to cervical or endometrial glandular cells or indicate whether the type of glandular cells cannot be clearly identified. Adenocarcinoma in situ has been separated as another distinct category of diagnosis (6). This change has been made in order to better reflect current knowledge and understanding of glandular neoplasia.

Glandular abnormalities represent a challenge not only for the cytologist but also for the colposcopist, with the possibility of missing or misdiagnosing them. This leads to poor sensitivity or specificity of colposcopy in glandular lesions. The clinicians have a difficult task to gain a balance between under or overtreatment of AGC cytological diagnosis. The aim of this study is to document the experience of the colposcopy in cases with AGC in our clinic and to propose new strategies in order to achieve a better management of AGC diagnosis.

MATERIAL AND METHODS

Beginning from 01.01.2001 till 01.01.2014, there were 97 referrals with AGC in our colposcopy clinic. Information regarding age, clinical indication for taking the Babes-Papanicolau smear, clinical history, colposcopy diagnosis and pathological report were extracted from our database. We excluded patients where we had no final report or where the follow-up was not possible (19 patients). All cases were followed for a period of at least 36 months after the diagnosis of AGC on Pap smear. The total number of cases included in the study was 78 (72 cases with AGC-NOS and 6 cases with AGC-FN). Data were analyzed using the statistical package *SPSS*. All patients give informed consent for biopsy. An internal review board for ethic approved the study.

RESULTS

The mean age of the patients were 41 years old +/- 12.3 years SD and the clinical indications for Pap smear are as follows (tab. I) .

TABLE I

Indication for Pap smear

Indication for Pap smear	Number of patients	%
Routine (opportunistic screening)	36	46.2%
Abnormal bleeding	18	23.1%
Cervical pathology in history	24	30.7%
Total	78	100%

The colposcopy exam was satisfactory (columnar squamous junction visible, with transformation zone type I and II) in 65 cases (83.3%). In 13 cases (16.6%) the colposcopy was unsatisfactory (transformation zone type III). All patients with unsatisfactory colposcopy where in menopausal status.

The colposcopy findings are presented are the following (tab. II). In 4 cases (5.1%) we had suspicion of glandular lesion, represented by white areas in the columnar epithelium.

TABLE II
Colposcopy findings

Colposcopy findings	Number of cases	%
Normal findings	44	56.4%
Minor findings	8	10.2%
Major findings	12	15.4%
Suspicion of invasion	1	1.3%
Unsatisfactory	13	16.6%

Histology was obtained through excisional procedures (loop electrosurgical excision procedure or conization) in 24 cases and diagnostic procedures (punch biopsy) in 54 cases. In 34 cases (43.6%) we performed a cervical curettage and in 44 cases (women over 35 years old or with abnormal bleeding) we performed both cervical and endometrial sampling.

The pathological reports are presented in tab. III. In 53 cases the pathology results were normal or had benign changes, while in 25 cases the results showed abnormalities.

TABLE III
Pathological findings

Histology findings	Number of cases	%
Normal findings	53	67.9
Low-grade cervical lesion	10	12.8
High-grade cervical lesion	8	10.3
Adenocarcinoma in situ	2	2.6
Invasive carcinoma	5	6.4

DISCUSSION

Cervical cytology is the only current detection method for cervical glandular neoplasia, but its sensitivity is poor (7). Although the natural history of glandular cervical lesions is poorly documented, several studies in the literature indicate that AGC Pap smear results are associated with a high frequency of underlying high-grade cervical neoplasia or cancer (8, 9). The prevalence or short-term cumulative incidence of invasive gynecologic cancer varies from 1% to 8% in follow-up women with AGC (8, 9, 10).

Because of the risk of a gynecologic neoplasia, direct referral for colposcopy, endocervical or endocervical plus endometrial exploration is indicated when a cytological result of AGC or endocervical adenocarcinoma in situ (AIS) is reported. Endometrial sampling is recommended when: glandular lesion is qualified as being endometrial on cytology report, women is older than 35 years or in cases with abnormal vaginal bleeding (11).

Although in all cases with AGC on Pap smear colposcopy is mandatory, in the literature much debate continues with regard to the colposcopy findings in glandular lesions. There are no obvious colposcopy features that allow definite diagnosis of AIS and adenocarcinoma. Colposcopy is useful to differentiate between normal and abnormal epithelium in squamous cervical lesions. For glandular lesions there are no firm and widely accepted criteria. Many colposcopist consider that glandular intraepithelial neoplasia has no specific colposcopy features and colposcopy with punch biopsy has little role in their precise diagnosis (12). However, everybody agrees that diagnosis by colposcopy, of AIS and adenocarcinoma require a high level of experience and skill. Colposcopists can be trained to suspect where to suspect the presence of an adenocarcinoma in situ or invasive, but confirmation always requires histology.

In our study the association with invasive cancer, adenocarcinoma in situ and high-grade cervical lesions was: 6.4%, 2.6% and respectively 10.3%. Our data are concordant with those from the literature. In cases where colposcopy was satisfactory,

minor and major colposcopy changes were present in 10.2% and respectively 15.4% of cases. The colposcopy was useful in cases where the final diagnosis comprised a squamous intraepithelial lesion. In only 4 cases we observed colposcopy changes suggestive for glandular lesion, and the histology confirmed the glandular involvement in one case. In 13 cases colposcopy was not useful, because the columnar junction was not observed and all of these cases where menopausal patients. In one case colposcopy was normal, but conization revealed adenocarcinoma in situ. This could be explained by the fact that cervical glandular neoplasia may be focal within the endocervical canal rather than arising at the transformation zone (skip lesions). On the other hand, we had 53 patients (67.9%) with negative histology and this may represent an overtreatment induced by the possibility of having CIN.

Patel and col. showed that a normal, satisfactory colposcopy has a negative predictive value of 100% and they can confidently exclude any cervical abnormalities in women under 35 years of age (13). These data are not supported by the study of Chumen because they discovered CIN in patients younger than 35 years old with AGC but normal colposcopy. According to their study the specificity of colposcopy is poor in young patients with AGC (14).

Due to the difficulties that can arrive with colposcopy it is obvious that there is need for new strategies for management of AGC in order to avoid the overtreatment but in the same time not to miss asymptomatic cervical intraepithelial lesions. A possible tool could be represented by Human Papilloma Virus (HPV) typing. While HPV typing is a well and recognized test for detecting squamous CIN, insufficient data are available concerning the performance of HPV testing in glandular cervical lesions. HPV detection was strongly associated with the presence or severity of cervical lesion (CIN 2 or worse) in women referred for AGC or AIS in their Pap smear. These data suggest the use of HPV testing in triage of women with AGC Pap smears (15, 16). In endocervical lesions HPV test could be a valuable tool to decrease the number of diagnostic procedures with its related morbidities but further studies are needed in order to establish the exact place of HPV typing in management of the cytological diagnosis of AGC (17). HPV testing has several limitations and one of them is the inability to diagnose non-related HPV lesions such as endometrial adenocarcinoma. The incidence of endometrial abnormality in AGC Pap smear is ranging from 10% to 40% (14, 18). HPV test is not useful in cases with endometrial abnormalities. A very important role here is the cytologist examination who should specify the origin of the cell: cervical or endometrial. Also, the age could be a predictive factor for the origin of the lesion: younger women most often, have endocervical lesions, whereas endometrial carcinoma generally occurs in older women. Women at risk for endometrial or extra uterine malignancies should undergo appropriate evaluation regardless of HPV status (16). The new cervical screening program introduced in Romania will increase the number of cases with ACG and in clinical practice a proper management of these cases is very important (19, 20).

The main limitation of our study is that we do not have an HPV test applicable to all patients due to the fact that the test is not free of charge and only a small number of patients could afford it. It would be of interest to perform more studies, to see if HPV test could be implemented in the management of AGC, and how this test will reduce, the number of invasive procedures used for the diagnosis.

CONCLUSIONS

The cytological diagnosis and management of AGC represents a challenge not only for the cytologists but also for the clinicians and all women with AGC on cervical cytology require immediate referral for colposcopy and assessment by an experienced gynecologist. Colposcopy is very useful if squamous cervical lesions are associated. New strategies are needed in order to increase the accuracy of the diagnosis and management of glandular lesion and HPV test could be useful for glandular cervical lesions, but the place of this test should be clarified by further studies.

NEWS

PLACENTA ACCRETA FOLLOWING HYSTEROSCOPIC LYSIS OF ADHESIONS CAUSED BY ASHERMAN'S SYNDROME: A CASE REPORT AND LITERATURE REVIEW

Asherman's syndrome is defined as partial or complete obstruction of the uterine cavity primarily caused by intrauterine procedures and infections. Hysteroscopic adhesiolysis is commonly used to treat Asherman's syndrome. Although the frequency of placenta accreta is known to increase with pregnancy after hysteroscopic adhesiolysis, precise data remain unknown. We report a case of placenta accreta following hysteroscopic lysis of adhesions caused by Asherman's syndrome and IVF treatment and review the literature on placenta accreta following hysteroscopic adhesiolysis. It is necessary to consider placenta accreta as a complication of pregnancies after hysteroscopic adhesiolysis for Asherman's syndrome, particularly in those conceived using IVF. The incidence of placenta accreta is significantly higher in IVF pregnancies than in spontaneous pregnancies. Esh-Broder *et al.* reported that the rate of placenta accreta in spontaneous pregnancies was 12/752 (1.2/1,000), while that in IVF pregnancies was 30/24,441 (16/1,000). The higher rate of placenta accreta in IVF pregnancies may be due to the change in endometrial environment and morphological and structural changes to the endometrium due to the IVF treatment protocol (stimulation protocol). Intrauterine adhesions (IUA) severity is associated with greater reduction in fertility thereby increasing the likelihood that affected patients will need to undergo IVF to have a successful pregnancy. The extent of endometrial loss increases with IUA severity, which likely confers a greater risk of placenta accreta. For this reason, doctors should be aware that IVF pregnancy following hysteroscopic adhesiolysis involves a greater risk of placenta accreta (Yuko Sonan,S Higeru Aoki *et al.*, Placenta accreta following hysteroscopic lysis of adhesions caused by Asherman's syndrome: a case report and literature review, *Case Reports in Obstetrics and Gynecology*, 2018; https://doi.org/10.1155/2018/6968382)

THE USE OF FUZZY LOGIC IN CANCER DIAGNOSIS - REVIEW

THE USE OF FUZZY LOGIC IN CANCER DIAGNOSIS-REVIEW (Abstract): Cancer has always been a disease difficult to fully comprehend by researchers because both of the genetic and environmental factors as well as the complexity of the human organism. Scientific and technological developments alongside the trend of multidisciplinary approach have enabled the acquisition of new medical knowledge as well as employing new diagnostic or treatment tools. Such could be the example of the use of artificial intelligence in the diagnosis or management of certain diseases. This paper emphasizes on the use of fuzzy logic in cancer diagnosis. The main issue addressed is early diagnosis by identifying at-risk individuals through risk factor assessment. The types of cancer chosen were those with the highest incidence and mortality worldwide: lung, breast, prostate, colo-rectal and gastric cancer. Using an artificial intelligence program along the patient database could quicken and optimize the referral of at-risk individuals to specialists, which in turn could improve the diagnosis of early stage cancer disease, thus reducing mortality and morbidity. **Keywords**: CANCER, DIAGNOSIS, FUZZY LOGIC.

The evolution of science and technology is characterized by an exponential growth in the last centuries alone. Acquiring new scientific knowledge prompted the development of new technologies, which in return, through a positive feed-back, helped enrich scientific knowledge. The physical world around us has been demystified and structured into constituent parts, patterns all governed by clearly stated laws. Yet complex systems still represent an issue to scientist as they are very difficult to describe and rationalize. Examples of complex systems are the living organisms, ecosystems, climate of the earth, social organizations. To be able to describe such a complex system first requires identifying all the separate parts of the system. If we take into consideration the ultimate parts of this system (i.e. atoms) then we encounter one of the first problems: the collection, storage and management of big data. From this derives the second issue: the more constituent parts there are, the higher the computational complexity is. All this without considering the different relationships between the separate parts.

Considering that the complex systems are not static and inside them are multiple patterns and events of variable magnitude,

ever shaping the whole system, it is extremely difficult firstly to correctly identify these events but also to try to formulate universal laws which should apply to the system. In order to tackle these issues and be able to analyze and predict the behavior of a complex system there are two logical solutions. First, which is highly dependent on technological advances, is the improvement of electronic computers to be able to work faster and with immense amounts of data. The other is an interdisciplinary research drawing inspiration from natural computing systems, such as the nervous system. One example is represented by fuzzy logic, which uses both mathematical tools and also words, much alike the human thought process (1).

FUZZY LOGIC

To better understand fuzzy logic, it is necessary first to explain the concept of Boolean sets. These sets, also known as "crisp" sets, are fall under the Law of the excluded Middle formulated by Aristotle, which is also the foundation of the binary system. According to this law, one element can be part of a specific set or not. If we refer to the binary system, 1 means that the element is wholly part of the set or 0 means it is wholly excluded from the set. Fuzzy mathematics was first described in 1965 by Lofti Zadeh. A fuzzy set represents a shift in the binary system paradigm. An element can at the same time belong or not to specific set. This is referred to as a degree of membership. This degree of membership can be a real number included between 0 and 1. If the degree is 0 the element does not belong to the set and if it is 1 then the element completely belong to the set. Anything in between means that the element partially belongs to that set.

In creating a Fuzzy Logic System, multiple fuzzy sets and be connected through AND, OR, NOT operators and afterwards rules must be applied to this logic. These so-called fuzzy rules describe a relationship between input and output fuzzy sets using operators such as IF-THEN (2).

Fuzzy logic systems have structural and functional analogies with the human nervous system and also fuzzy logic mimics the human capabilities of computing with words. The classic examples often used are the sensory system and the fuzzy logic being a model of the human learning via patterns. Because of its unique traits, fuzzy logic systems are optimal for computing data which includes unknown variables and because of the way it derives from binary logic, it does no longer provide a qualitative output, rather a prediction, making it an ideal working tool for such a complex mechanism as the human body (3). The use of fuzzy systems was used with great success in a variety of medical fields. One of the newer uses is the cancer research. This was a logical application of fuzzy logic since variability is keyword in describing cancer. Etiologically we have a complex interaction between genetic factors and risk factors, either environmental or habitual, the correlation between them impossible to predict in a direct manner (with some exceptions such as familial polyposis). Variability is also a key word in disease progression, treatment response and morbidity.

PROSTATE CANCER

Diagnosis of prostate cancer requires three clinical tests: digital rectal examination (DRE), prostatic specific antigen (PSA) test and biopsy. The DRE is able to

raise the suspicion of the disease and can be useful in the staging by observing the local invasion. The PSA test is a quantitative test which measures the amount of this antigen in the patient's bloodstream. Interpreting the test on the other hand is more complicated. While high values of PSA usually correlate with the presence of prostate cancer, normal values do not exclude the presence of the disease. The biopsy is the only test which can provide the exact diagnosis of cancer and bring additional data such as Gleason score, thus revealing the aggressiveness of the cancer (4).

Considering PSA is the only screening tool available at the moment, there have been studies which try to improve the accuracy of this test using artificial intelligence. Such an example is using a hybrid between neural networks and fuzzy logic system in which the input data was PSA, free PSA value and a third data set with the age of the patients. All of the patients had elevated PSA but less than 20 ng/mL. Out of the 1030 men in the study, 195 had diagnosed prostate cancer. The neuro-fuzzy network provided superior predictive value compared to PSA or fPSA levels alone (95% sensitivity with 31.9% specificity) (5). There is also the foresight of FLS which could be able to differentiate between prostatic cancer and benign hypertrophy.

BREAST CANCER

There are many studies which focus on artificial intelligence tools for helping diagnose breast cancer. Image processing employing neural networks have successfully been used in early stage diagnosis. Apart from requiring important amounts of data to be able to train the program, it is also required that patients are referred to these imagistic explorations in the first place. This can be done either by implementing nationwide screening programs or by targeting specific susceptible individuals. One means of identifying at risk individuals is by using clinical data which is relevant in the case of this particular cancer such as age, body mass index, age of the menarche, age of the last menstrual period, age of first pregnancy and smoking. This helped create fuzzy sets to which there are rules applied afterwards and the output data represents the risk probability of breast cancer. The accuracy of this fuzzy system was 95%. Although there are limitations of this study such as patient selection it gives encouraging possibilities of future development of programs able to automatically identify at-risk patients. (6). Another study also used a fuzzy logic-based system to try to identify the patients with breast cancer from a specific group. Aside from patients age, age of menarche, age of first childbirth and age of menopause, data such as nutritional habits, regarding low or high fat diets, alcohol consumption and genetic risk factors were included. This method had 97%, sensitivity, which means that this method correctly identifies at risk patients, 64% specificity, which means the method employed correctly identifies the non-risk individuals and 81% accuracy (7).

COLON CANCER

The relationship between environmental and genetic factors in the etiology of cancer has always been an issue targeted by numerous studies. There are certain gene mutations which have been linked with various degrees of risk for developing cancer during the lifetime of these individuals. There are also environmental factors which

add to this genetic predisposition. But the relationship between these two can be described over a large spectrum. A good example is the hereditary non-polyposis colorectal cancer (HNPCC) or Lynch syndrome. Individuals bearing this autosomal dominant condition have a >70% risk of developing colorectal cancer (CRC) during their lifetime (8). Also, cigarette smokers male patients carriers of hMLH-1 mutations have an increased risk of up 2 times than nonsmokers (9). Using a model-free system, such as fuzzy logic seems ideal for assessing the risk of developing CRC of individuals with Lynch syndrome, with a great phenotypical heterogeneity and with multiple environmental risk factors. Considering members of the kindred are at risk of developing CRC anytime between the age of 25 and 65 and some may never develop it, a proven approach to cancer prevention (colonoscopy prevention versus prophylactic colectomy) is still lacking. A basic fuzzy logic system, with the rules refined using an Adaptive Neural Fuzzy Inference System, was able to identify high risk carriers of the hMLH mutations using as input data the type of mutation, gender, age and smoking status (smoker/non-smoker as well as number of pack-years) (10). Another basic fuzzy logic programs was designed to identify at risk population by using as input data symptoms which are generally ignored by patients such as weight loss, persistent abdominal pain, rectal bleeding and fatigue (11).

LUNG CANCER

Lung cancer represents the most common and primary cause of cancer death in the western world. Thus, early diagnosis through the measurement of biomarkers in target high risk population is of great importance in the management of these patients. The main issue with using biomarkers as screening method for lung cancer is represented by the low specificity or sensitivity of each marker taken individually. Therefore, the first step of improving sensitivity and specificity is to use a biomarkers panel rather that isolated measurements. The data acquired can then be analyzed by using fuzzy logic. This method had specificity of 97.4% and overall sensitivity of 73.6%. In the case of non-small cell carcinoma, this tool identified 70% of stage 1 and 92% of stage II cancers while in the case of small cell carcinoma the limited disease status was identified in 90.7% (12). The early stage diagnosis can be improved by employing other diagnostic tools such as computed tomography and sputum cytology analysis (13).

Apart from diagnosis, using a fuzzy-logic system with a specific biomarker panel (either using two-marker or three marker panels) can be used for the detection of tumor progression in small cell lung carcinoma with sensitivity up to 67% (14).

GASTRIC CANCER

Gastric cancer is ranked sixth among most common cancer types and ranked third among causes of cancer death with 738 000 deaths per year. As is the case of all cancer types, early diagnosis is very important in order to reduce mortality and morbidity. But gastric cancer remains asymptomatic or accompanied by nonspecific symptomatology until late stages of the disease with local advanced disease or in the presence of metastasis. The treatment is also an issue because gastric cancer seems rather resistant to chemotherapy and

even newer, more aggressive surgical options available such as Hyperthermic Intraperitoneal Chemotherapy (HIPEC) are not proving as successful comparing to other cancer types. In areas with higher incidence of gastric cancer, identifying the high and very high-risk population is of key importance for appropriate referral to a specialist and enabling early diagnosis. A fuzzy rule based Mandami expert system developed by Safdari *et al.* was used to identify the risk levels of a group of individuals and then the results compared with experts opinion. The input data consisted of medical history (*Helicobacter pylori* infection, gastric atrophy, gastric ulcer, gastric surgery, pernicious anemia, family history), socio-demographic factors (age, gender, level of literacy), smoking factors, nutritional factors (vegetable and food intake, content of nitrate compositions). The sensitivity of the method was 92.1% and the specificity was 83.1% (15).

DISCUSSION

Globally cancer is responsible for 1 in 6 deaths, being the second leading cause of death. Despite of all research conducted, it is very difficult to reduce these statistics firstly because of the great phenotypical heterogeneity and the lack of symptoms in early stages of the disease. Therefore, an attempt for the prevention of the disease is to identify the at-risk population and introducing screening to this population group. If we consider the multifactorial aspect of the disease and the hard to describe interaction between genetic and environmental risk factors, or the combined effect of various risk factors, the task of correctly identify the patients bearing these disease in the early stages becomes almost impossible. This issue can be easily solved by introducing population-wide screening tests specific for the most common type of cancer in that particular wise, but globally this is an impossible task, firstly considering the expense and the lack of specialists in different areas. A solution can be the use of artificial intelligence, such as fuzzy logic. This model-free system, which is capable of solving problems with a high degree of incertitude, seems a perfect tool to be used for this purpose. Considering it requires a simple patient database, using various input parameters it can assess the degree to which a patient might be at risk. The input parameter, as shown in the examples above, can be usual blood parameters or constitutional traits. Also, artificial intelligence programs can be used in certain grey areas of the diagnostic process, a clear example being a value of PSA between 4 and 10 ng/mL.

CONCLUSIONS

Early stage cancer is difficult to diagnose because of the lack of symptoms or presence of non-specific symptomatology usually ignored by patients. Therefore, patients usually are being diagnosed in late stages, in which treatment both oncological and surgical is limited and with higher morbidity and mortality.

Using an artificial intelligence program along the patient database could quicken and optimize the referral of these patients to specialists, which in turn could improve the diagnosis of early stage cancer disease. Fuzzy logic and neural networks already have proven as valid image processing tools aiding diagnosis, but they can also be used for identifying at-risk patients, with very good sensibility and specificity.

CLOSTRIDIUM DIFFICILE INFECTION-30-MONTH RECURRENCE RATE (Abstract) **Aim:** To evaluate the recurrence rate of *Clostridium difficile* infection (CDI) in the patients admitted to the Iasi "Sf. Parascheva" Infectious Diseases Hospital. **Material and methods:** Observational retrospective study of the patients admitted between January 1st, 2017 and June 30th, 2019. **Results:** Of the total of 736 patients diagnosed with CDI and admitted to our hospital 240 were included in this study. According to the number of CDI recurrences, 63.81 % of the patients experienced a first recurrence of CDI, over 20% a second recurrence, and the remaining patients a third to sixth recurrence. **Conclusions:** CDI is still a serious problem and a major burden on both the healthcare system and the patient. The causes of recurrent CDI are unclear. **Keywords**: *CLOSTRIDIUM DIFFICILE* INFECTION, RECURRENCE, TREATMENT.

One of the most common cause of nosocomial diarrhea is *Clostridium difficile* infection (CDI) which increases mortality and morbidity in hospitalized patients (1). Clinical symptoms of CDI range from asymptomatic carrier to mild and severe diarrhea, which can lead to fulminant colitis, toxic megacolon, bowel perforation, sepsis, and ultimately death (2).

Approximately 25% to 33% of antibiotic-associated diarrhea and 90% of pseudo-membranous enteritis are caused by CDI (3).

Although there are guidelines for the diagnosis and treatment of CDI, the infection rate continues to increase in Europe and United States. It is a known fact that there has been an enormous worldwide increase in the incidence and severity of CDI over the past 2 decades despite the prevention programs implemented in many countries (2).

In Europe, CDI costs healthcare services from 5,790 euros to 11,202 euros per episode (4) and the annual rate of recurrent CDI (rCDI) is between 75,000 and 175,000 cases (5).

Major risk factors for CDI in the general population are well known and they include antibiotic exposure (6) proton pump inhibitor (PPI) use, previous and prolonged hospitalizations, (7, 8) chemotherapy, immunocompromising conditions, and advanced age (9).

Studies have shown that the risk of recurrence after a first CDI episode is between 20 and 35%, and of these, 40-60% will ex-

perience a second recurrence (10). The course of the infection is influenced by the personal characteristics of the patient (risk factors, associated diseases) and the speed and accuracy of the treatment (11, 12).

CDI recurrences reduce the quality of life and also can place a major burden on healthcare system. Also, the social burden that comes with CDI has a considerable impact on patient's psychological state.

MATERIAL AND METHODS

We conducted an observational, retrospective study of the patients admitted to the "Sf. Parascheva" Infectious Diseases Hospital over a period of 2 and half years (January 1st, 2017 - June 30th, 2019). Out of a total of 736 patients that were admitted for CDI, we included in our study group 240 patients who had been previously admitted for CDI and presented for the recurrence of more than 3 diarrheic stools.

Data on the number of recurrences, associated diseases, length of hospital stay, presence or absence of the specific toxins, administrated treatment, and if they were transferred from another hospital were collected from the medical records of the patients.

RESULTS

Of the 736 patients admitted to our hospital with CDI from January 2017 to June 2019, 32.61% (240 cases) were admitted for recurrent CDI. Patient age ranged from 1 to 96 years old (mean age 68.5 years old). Patients were primarily urban (60.25%) and predominantly women (58.3%).

After reading the medical records of the patients we found that , 63.81% of the patients were at the first episode of , 20.57% developed a second recurrence, and 15. 62% a third to sixth.

In 92 (38.33%) cases, CDI recurrence occurred while the patients were admitted to other medical departments, fact requiring their transfer to our hospital (fig. 1). We found a high number of referrals by other small infectious diseases hospitals in the territory, gastroenterology, pulmonology, surgery and cardiology departments.

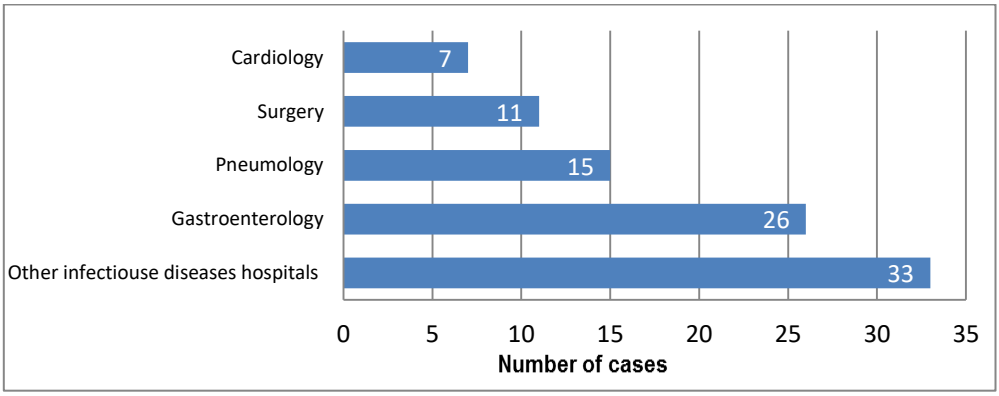

Fig. 1. Distribution of transfers to our clinic

We were interested to find the comorbidities of the studied group. Leading associated pathologies were cardiovascular diseases which were founded as a secondary diagnosis in 60 patients (25%) followed by metabolic diseases in 38 cases, liver diseases in 34 cases and gastroenterological diseases- 31 cases (fig. 2).

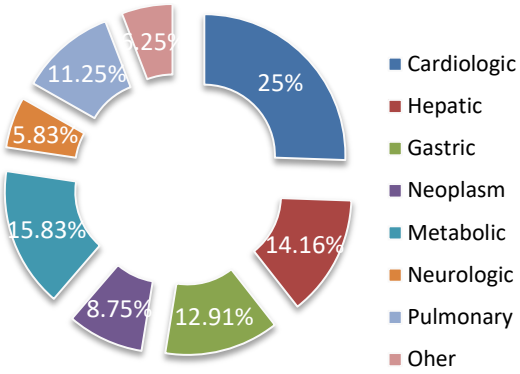

Fig. 2 Comorbidity of the patients

Analyzing the length of hospital stay, most of our study patients were admitted for more than 10 days, with a mean of 12.1 days (Fig 3). Over 50% of the admitted patients required more than 10 days of hospitalization and continuous supportive treatment. In 32 cases more than 15 days of hospitalization were necessary because of the severity of the disease.

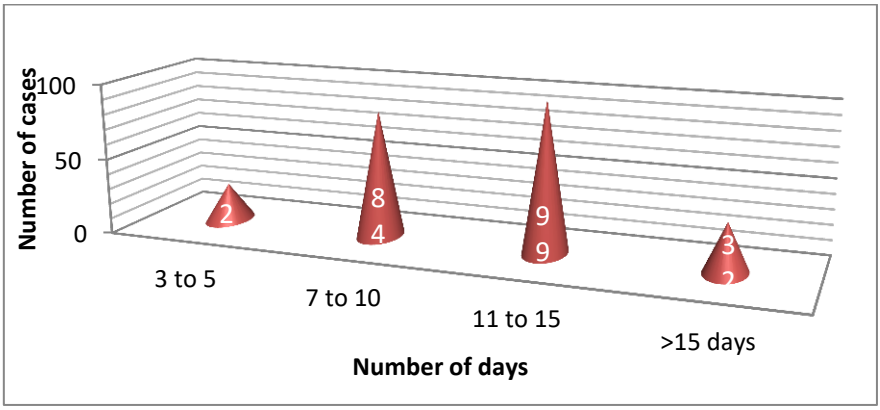

Fig. 3. Number of days of hospitalization

In our study group, 166 of patients received vancomycin (69,16%), followed by vancomycin-metronidazole (8.75%) combination therapy. In 62 cases rifaximin was administered alongside vancomycin treatment.

Cadazolid/vancomycin combination was administered in 3 cases, and fecal microbiota transplantation (FMT) was also performed in 3 cases (fig.4).

The diagnosis was made based on the results of the laboratory tests. In our study group, 26 cases were positive for toxin A alone, and 6 cases for toxin B alone, 8 cases were negative for both A and B toxins, 7 cases had only a positive GDH test, and the remaining 193 patients were positive for both of the toxins (fig. 5).

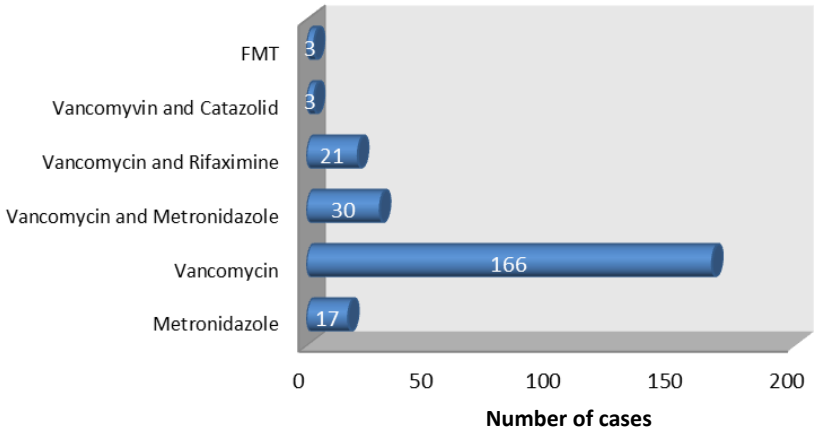

Fig. 4. Administrated treatment

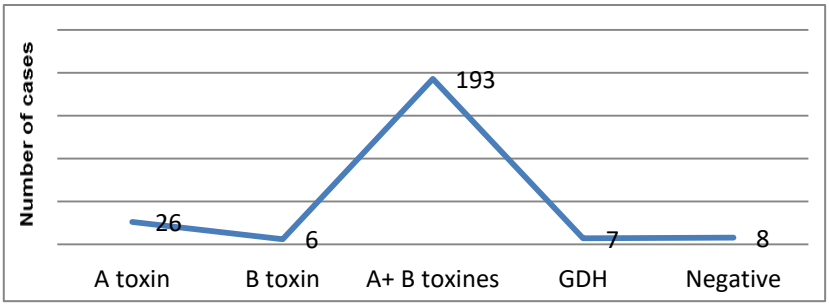

Fig. 5. Results of the laboratory tests

DISCUSSION

Studies have showed that the recurrence rate of CDI is situated between 20% and 35%.

In the presented study the rate of recurrence was closely to the higher value and situated at 32.60% (10). According to the already published data, the female gender has a higher predisposition to CDI (4) data that also applies in our study in which 58.3% of the admitted patients were woman.

Advanced age is one of the most frequent risk factors for recurrence of CDI (17). Even though we included in the study patients of all ages, we could observe that the majority of the patients were people with age over 60 years old with an average age of 68.5 years old and with at least one underlying diseases.

The performed studies (4, 18) correlate that approximately 37% of CDI have the onset on a health-care facility. In our study, 38,3% of the cases admitted in our clinic were transferred from other hospitals. CDI poses a great burden (4) not only on the healthcare system but also on the patient. The patients with multiple recurrences had experienced depression linked to the gravity of the disease directly proportional to the severity of the illness.

In some cases, the intervention of the hospital psychologist was required. The

role of this medical intervention is to minimize the burden of this debilitating disease (14, 15).

More than half of the patients (54.58%) required more than 10 days of hospitalization. The advanced age and the underlying diseases make the patients susceptible to rCDI due to immunocompromised state, which complicates the evolution of the disease. The result of all that is a prologue hospitalization. (16, 19).

After advanced age, comorbidities, use of antibiotics after CDI diagnosis, inadequate immune response, and concomitant receipt of acid-suppressive therapy are considered risk factors for rCDI. In our study the main associated diseases were cardiovascular, metabolic, liver and gastric pathologies. (17)

The primary cardiovascular pathologies that the patients associated in 25% of the cases were hypertension and cardiac insufficiency. The metabolic diseases were represented by diabetes mellitus and obesity and were found as a secondary diagnosis in 15.83% cases. The most frequent hepatic diagnosis was represented by hepatic cirrhosis and chronic hepatitis in 14.16% of the cases. Gastroenterological pathologies were found in 12.91% of the patients and consisted in ulcers, gastritis and acid reflux. We have to mention that 21 patients associated different types of neoplasm (prostate, colon, uterus, breast). Associated diseases are risk factors for CDI, aggravating the progression and prolonging hospitalization (13).

Studies showed that the majority of relapses are due to recurrences of CDI with the original strain rather than reinfection with a different. The management of an initial CDI recurrence includes repeat administration of either oral Metronidazole (500 mg every 8 hours) or vancomycin (125 mg every 6 hours) for10-14 days (10).

In our study group, the majority of patients received vancomycin, followed by vancomycin/ metronidazole combination therapy. In a few cases rifaximin/vancomycin combination therapy was used.

The diagnosis of CDI requires both clinical symptoms and a positive laboratory test. Several methods are recommended for the diagnosis of CDI, including toxicogenic culture, enzyme immunoassays (EIAs) for toxins A and B, and/or glutamate dehydrogenase (GDH) (13). In the studied group both toxins (A and B) were present in 54.48% of the cases (193 cases). In 10.83% of the samples just the A toxin was present and in 2.5% of them only the B toxin was positive. The rest of the sample presented no toxin or a nontoxigenic strain.

Multiple CDI recurrences and prolonged hospital stays can result in patients feeling or being stigmatized by society and even by their close family. A lot of these patients requires psychological support because of the depression caused by this “chronic” illness (14, 15).

Medical world should start focusing on new molecules for treatment of the disease. The presence of multiple comorbidities in the elderly population makes us expect a dramatic increase in the number and severity of CDI cases that could ultimately become resistant to usual treatment (20).

CONCLUSIONS

Over the last 20 years there has been a substantial increase in the number of CDI cases. The first CDI recurrence causes substantial morbidity and is a major burden on healthcare systems. Minimizing the number of recurrences can reduce the social, psychological and medical burden on patients and healthcare systems.

Even if the treatment is administered according to the protocols, approximately one third of the patients experience a recurrence of the infection.

2. PhD student at "Gr.T. Popa" University of Medicine and Pharmacy Iaşi

SOCIOECONOMIC IMPLICATIONS OF UNDERDIAGNOSING TEENAGERS' DEPRESSION (Abstract): The aim of our research was to demonstrate once again that teenagers' depression still remains way too much underdiagnosed, the last one having important socioeconomic implications. Thus it is absolutely necessary to implement depression screening in psychiatric clinics. **Material and method**: The study was carried out in 2 stages, I; a group of 1126 in-patients from "Sf. Maria" Hospital, and II the analysis of the socioeconomic implications of teenagers' depression. **Results**: Only 19, 11% of the depressive patients had a previous depression diagnosis, the rest of 80, 89% were new cases, recently diagnosed; the depressive teenagers are more exposed to drugs and alcohol abuse, to antisocial behavior, and to poorer results in school. **Conclusion**: Screening depression implementation would reduce very much the risk of teenagers' depression underdiagnosing. **Key words**: DEPRESSION, TEENAGERS, PEDIATRICS

ANALYSIS OF THE OUTCOMES OF PREGNANCIES OBTAINED AFTER INFERTILITY TREATMENT, IN "CUZA-VODA" HOSPITAL FROM IASI, ROMANIA

Adina-Elena Tănase[1], B. Toma[1*], Loredana Himiniuc[1], Mirabela Petică[2], D. Hutanu[2], M. Onofriescu[1]

[*]Corresponding author. E-mail: toma.bogdanf@gmail.com

ANALYSIS OF THE OUTCOMES OF PREGNANCIES OBTAINED AFTER INFERTILITY TREATMENT, IN CUZA-VODA HOSPITAL FROM IASI, ROMANIA (Abstract): The prevalence of infertility is raising nowadays, affecting 15% of couples in their reproductive age. It has significant medical, social, and financial implications. It is estimated that 2-3% of all births in developed countries are the result of IVF procedures. The demand for assisted reproduction techniques is constantly increasing, and there is a continuous need to develop more efficient and less harmful protocols. **Materials and methods:** The descriptive, retrospective analytical study was performed on a group of 657 pregnant women with infertility treatment followed before pregnancy, who gave birth in the Department of Obstetrics-Gynecology of "Cuza-Voda" Hospital in Iasi, between 2010 and 2018. **Results:** No comorbidity was noted as a good predictor in the determinism of low birth weight, which led to the conclusion that infertility treatments do not independently influence the prognosis of birth weight in girls in our study group (AUC<0.600). **Conclusions:** The expected outcome of infertility treatments is highly dependent on the effectiveness of controlled ovarian stimulation, a routine procedure prior to IVF, and the results obtained must be constantly analyzed in order to be improved for the benefit of patients. **Keywords:** INFERTILITY TREATMENT, PREGNANCY, *IN VITRO* FERTILISATION.

Each year around 1.5 million cycles of assisted reproductive medicine (ART) are reported worldwide, with a ratio of 333,000 children born. The figures represent about 70% of all infertility treatments. Thus, about 2.4 million ART cycles are estimated each year, with about 500,000 children born (1). The outcomes after infertility treatment are the result of a multidisciplinary team formed by the specialist in ovarian stimulation treatments, embryologist, and obstetrician, and require careful monitoring in collaboration with different medical specialties in high risk patients (1).

The newborns, in numerous studies, have the same prognosis for development as in the general population, but an important knowledge of maternal comorbidities must be realized, these risk factors being independent of the neonatal ones (2,

3). In current practice, single embryo transfer *in vitro* fertilization protocols is preferred (4, 5, 6), to reduce the risk of these neonatal complications, which are higher in twin pregnancies (7, 8).

MATERIALS AND METHODS.

The descriptive, retrospective analytical study was performed on a group of 657 women, between 18 to 50 years old who underwent infertility treatment in infertility clinics, either from Romania or abroad and became pregnant after controlled ovarian stimulation (COS) protocols. From the total, we excluded stillbirths and we obtained a number of 626 live births. The treatments that infertile patients followed were either mono ovulatory stimulation, intrauterine insemination(IUI), *in vitro* fertilization (IVF) or intracytoplasmic sperm injection (ICSI), resulting with live birth pregnancies. All the fetuses following these procedures were born in the Department of Obstetrics-Gynecology of "Cuza-Vodă" Hospital from Iasi, between 2010 and 2018.

Statistical analysis was performed in *SPSS 20.0*. The existence of a relationship between variables was evaluated with the Pearson correlation coefficient, p, Skewness and Kurtosis tests.

RESULTS

Analyzing the data from each year, following infertility treatments, we found a slightly increasing trend of number of births (y=14.658+12.08 x), with a frequency peak encountered in 2018 (18.1% of the total study group) (fig. 1), predicting for 2019 a number of approximately 135 births after infertility treatment (fig. 2).

In summary, in 2018, there were 31 singleton natural births (NAT) (1.23% of total live births) and 626 of total caesarean (CST) births (2.24% of total CST) after infertility treatment. Of all, just 11.2% were twins (tab. I, fig. 3).

Distribution by age groups. The corroboration between the mean age of 33.56 ± 4.47 years, the median 33 years, and the results of the Skewness (p=0.287) and Kurtosis (p=0.472) tests, suggest the homogeneity of the various values of mother's age with fertility treatment, showing that it can be applied significance tests for continuous variables (fig. 4). In this study, every year, about 10 to 30% of the mothers with infertility treatment were under 30 years of age (p=0.134).

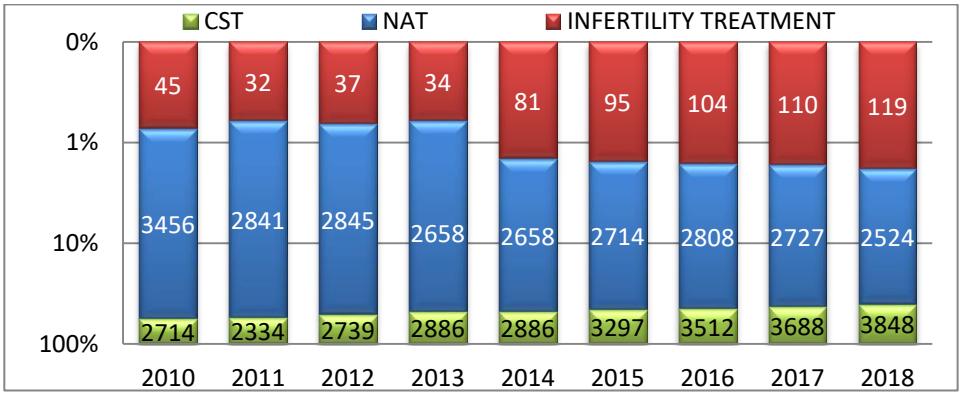

Fig. 1. Distribution of cases with infertility treatment of total live births between 2010 and 2018

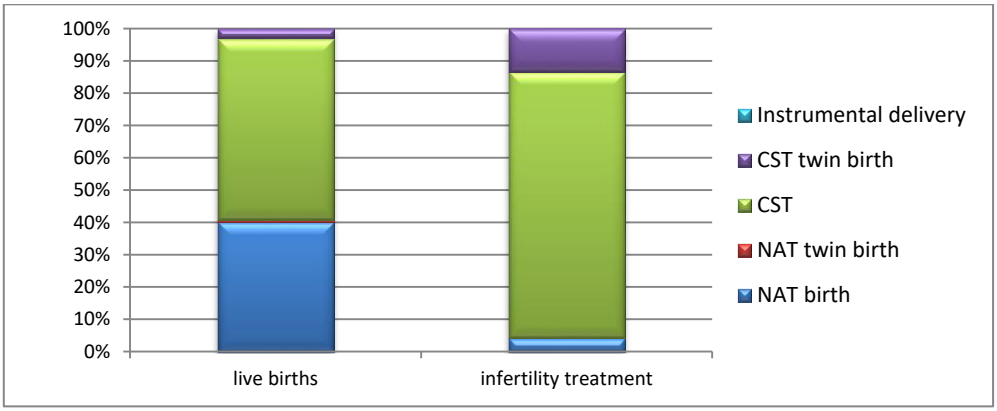

Fig. 2. The incidence of patients that followed infertility treatments from the total of live births in 2018

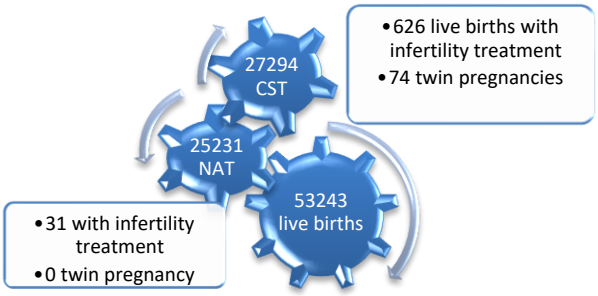

Fig. 3. Distribution of infertility treatments from total live births between 2010-2018

TABLE I

Annual incidence of births after infertility treatment

Year	Infertility treatment	% of patients with primary or secondary infertility	Live births	Patients with Infertility treatment per 1000 live births	NAT		CST	
					Total (% of live births)	Births After infertility treatment (% of total NAT)	Total (% of live births)	Births After infertility treatment (% of total CST)
2010	45	6.8%	6200	7.26	3456 (55.7%)	2 (0.06%)	2714 (43.8%)	43 (1.6%)
2011	32	4.9%	5186	6.17	2841 (54.8%)	2 (0.07%)	2334 (45.0%)	30 (1.3%)
2012	37	5.6%	5591	6.62	2845 (50.9%)	0 (0.0%)	2739 (49.0%)	37 (1.4%)
2013	34	5.2%	5558	6.12	2658 (47.8%)	4 (0.15%)	2886 (51.9%)	30 (1.04%)
2014	81	12,3%	5558	14,57	2658 (47,8%)	3 (0,11%)	2886 (51,9%)	78 (2,7%)
2015	95	14,5%	6022	15.78	2714 (45.1%)	2 (0.07%)	3297 (54.7%)	93 (2.8%)
2016	104	15.8%	6333	16.42	2808 (44.3%)	6 (0.21%)	3512 (55.5%)	98 (3.9%)
2017	110	16.7%	6422	17.13	2727 (42.5%)	7 (0.27%)	3688 (57.4%)	103 (2.8%)
2018	119	18.1%	6373	18.67	2524 (39.6%)	5 (0.20%)	3848 (60.4%)	114 (3.0%)
Total	657	100%	53243	12.34	25231(47.4%)	31 (1.23%)	27904 (52.4%)	626 (2.24%)

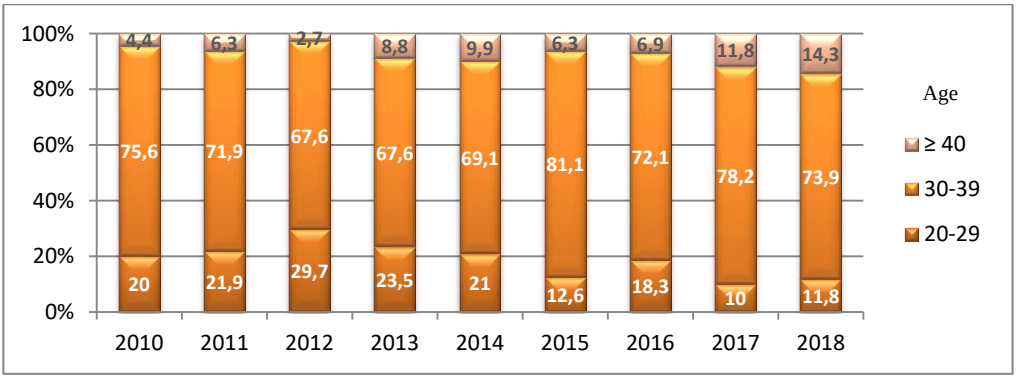

Fig. 4. The distribution of the patients by age and year of study

Distribution by environmental provenance. From the total study group, 74.6% of the mothers with infertility treatment came from the urban area, the ratio of Urban / Rural quotas being 3/1 (fig. 5)

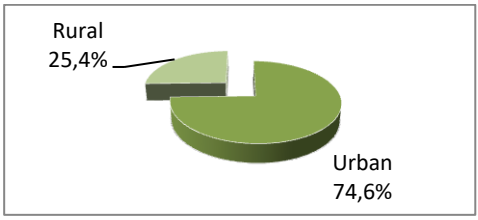

Fig. 5. Distribution of the patients by environmental provenance

Distribution by gestational age. The mean gestational age in mothers with infertility treatment was 37.40 ± 2.14 weeks, close to the median value (38 weeks). These values in corroboration with the results of the Skewness (p=-1.543) and Kurtosis (p=1.876) tests, suggests the homogeneity of the series of values of the gestational age, revealing that these significance tests can be applied for continuous variables (fig. 6)

About 9.7% of natural births and 5.3% of cesarean births in women with infertility treatment, were performed under 32 weeks of gestation (p=0.337) (fig. 7).

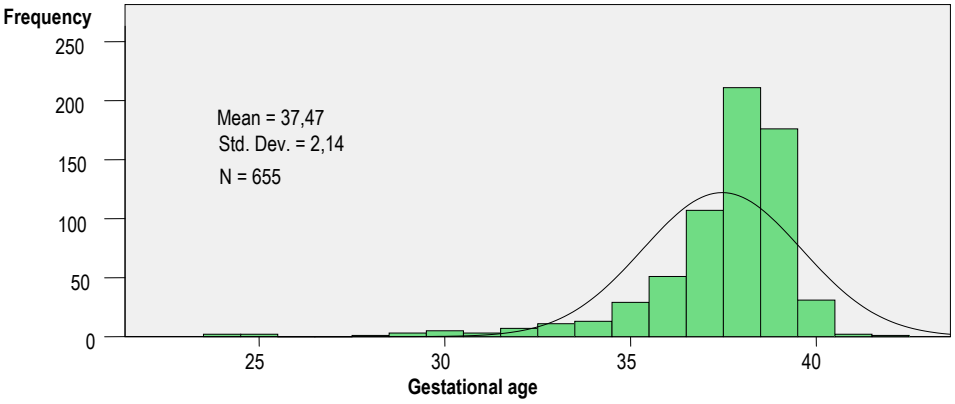

Fig. 6. The histogram of gestational weeks in patients with infertility treatment

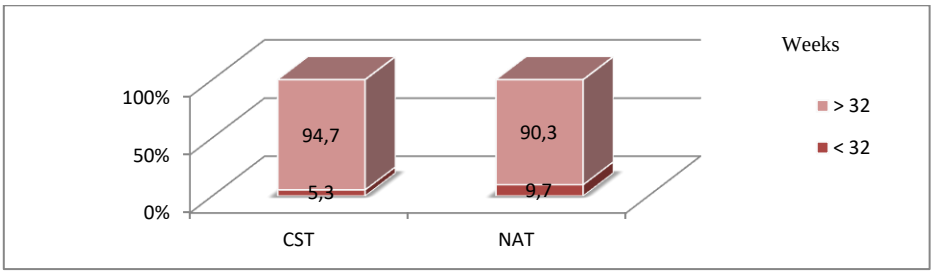

Fig. 7. The group structure patients by gestational age and type of delivery

From the total of patients included in this study, 75% of mothers with infertility treatment gave birth under 32 weeks of gestation and 6 days and 74.1% of these gave birth after 33 gestational weeks. The two groups were represented by women with ages between 30 and 39 years old, showing no statistical significance (p=0.605), thus observing the fact that women after 35 years old requires more often ovarian stimulation in order to achieve a pregnancy (fig. 8).

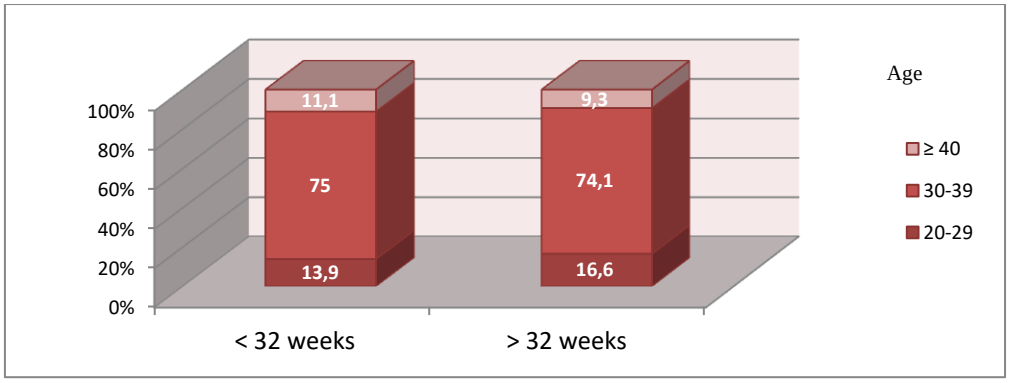

Fig. 8. The group structure by age groups and gestational ages

Applying the Pearson correlation to the case study, shows that the age of IVF mothers and the gestational age of their pregnancies were observed as apparent independent parameters (p=+0.007; p=0.849).

Weight at birth. The mean weight at delivery was 3,077 ± 642 g, closed to the median value (3,100g). Associating these results with the results of the Skewness (p=-0.911) and Kurtosis (p=1.810) tests, suggest the weight homogeneity of the series at delivery, so significance tests can be applied for continuous variables (fig. 9).

Associated pathologies. Of the total of possible comorbidities analyzed, the most commonly identified was hereditary deficiency due to the lack of coagulation factors, in 8.5% of patients, followed by gestational hypertension (6.8%), of which only 0.9% had complicated with various forms of pre-eclampsia, and liver disorders in (5.2%), being objectified by blood tests. Another common association were uterine fibromas that were found in 5.2% of patients (fig. 10).

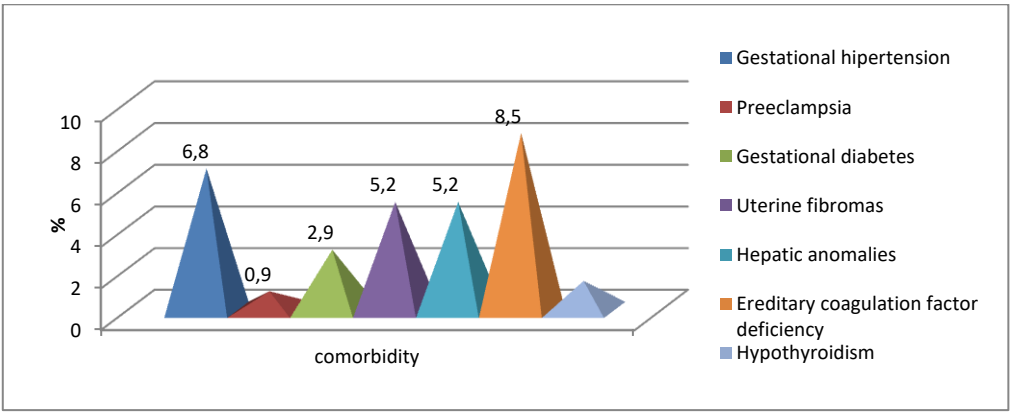

Fig. 10. Frequency of comorbidities

DISCUSSION

Once with the constant improvement of pregnancies and live births after IVF in the last two decades, these procedures has become a high successful treatment for female and male infertility, reaching maximum values of live births between 2001 and 2002 (9, 10). The live birth rates have hit a plateau, subsequently declining in regions of the world. Also, it is important to define how fast "industrialization" is at the global level, the transition from a model of individualized private practice per patient, to a global, generalized one, with greater profit for investors and "commercialization" in IVF practice, respectively the main focus of competition on revenues and not on IVF results (11).

In our study it is important to mention that the overall delivery rate was not lower when single embryo transfer was performed and that the multiple delivery rate (74 from a total of 657 pregnancies) which was 11.2% could have been very much lowered, as twin pregnancies are associated with many maternal-fetal complications.

Worldwide, increased live birth changes were associated with the introduction of new IVF practices, including light stimulation, elective single embryo transfer (eSET), PGS (pre-implantation genetic screening) for aneuploidy detection, total freezing cycles, and embryo banking (12,13). Isolated negative associations were associated with *in vitro* fertilization tasks in pathologies such as high blood pressure, abnormally adherent placenta, genetic abnormalities or isolated birth defects, or birth defects in Japan, Australia, New Zealand and Canada, where there is a consistent research base (14, 15).

CONCLUSIONS

In our study, we wanted to identify factors as good predictors of lower birth weight, below the 10th percentile, of gestational age, and correlations between patient characteristics and associated maternal-fetal complications. The patients that decide to conceive through IVF are becoming younger each year; therefore, this procedure will continue to rise among young couples.

On the other hand, women after 35 years old, have lower chances of conceiving spontaneously, and requires further investigations and infertility treatments. Regarding environmental provenance, we noticed a higher demand of such treatments from patients located in urban area, but we consider that with today's advertisements more women will demand infertility treatments in the nearby future.

We did not identify any co-morbidity as a good predictor in the determinism of low birth weight, which led to the conclusion, of our study, that infertility treatments do not independently influence the prognosis of birth weight and neonatal adaptation. These aspects are important to reinforce in our medical practice, because women that require infertility treatments in order to obtain a pregnancy are more prone to social isolation and marital problems before the conception that can affect their quality of life. It is important to mention that medicine must be redirected from the general approach to the individualized one on the patient, especially in patients that struggle to obtain pregnancies.

NEWS

TRADITIONAL CHINESE MEDICINE USED ON PATIENTS WITH RHEUMATOID ARTHRITIS: ALTERNATIVE OR COMPLEMENTARY TREATMENT?

The use of traditional Chinese medicine (TCM) on patients with rheumatoid arthritis (RA) had a magnitude of 30% as compared to the general population of Taiwan, according to the results of retrospective cohort study used the Longitudinal Health Insurance Database (LHID) 2000. The authors, Ming Chi-Lu and colleagues, aimed to describe the utilization of TCM and determine the factors related to TCM usage among RA patients. Herbal remedies (49.6%) constituted the most commonly used therapeutic approach, followed by combined therapy (32.7%) and acupuncture or traumatology manipulation alone (17.7%). The profile of the patients who used TCM is female, younger age, higher monthly income and higher Charlson-Deyo co-morbidity index scores, living in urbanized areas, in higher TCM physician density. The top three reasons for seeking TCM services were diseases of the musculoskeletal system and connective tissue, the respiratory system, and the digestive system (Lu M C, Livneh H, Chiu L M, Lai N S, Yeh C C, Tsai, T Y 2019. A survey of traditional Chinese medicine use among rheumatoid arthritis patients: a claims data–based cohort study. *Clinical rheumatology*; *38*(5): 1393-1400).

PSEUDOTUMORAL TUBERCULOSIS AFTER 13 MONTHS OF ADALIMUMAB. CASE REPORT

PSEUDOTUMORAL TUBERCULOSIS AFTER 13 MONTHS OF ADALIMUMAB. CASE REPORT (Abstract): In patients with chronic immune-mediated inflammatory diseases, biological therapy targeting the components of the immune response acts like suppressive agents of the host immune system, being associated with increased risk of opportunistic infections and tuberculosis (TB). The case of a 35-year-old male patient, active smoker, with chronic psoriasis, previously treated for 13 months with the tumor necrosis factor α (TNF-α) inhibitor adalimumab is reported. The patient was admitted for a peripheral lung mass localized in the left upper lobe, associated with mediastinal lymphadenopathy, highly suggestive of lung cancer. Sputum smears and bronchoalveolar lavage were negative for acid fast bacilli, but tuberculin skin test (TST) results converted from negative to positive in the last 13 months. Histological description of lymph node biopsy revealed sarcoidosis. Due to the discrepancy between positive TST, imaging and histological results, surgical open lung biopsy was considered. Atypical segmental resection was performed, and the final histological diagnosis was TB. In conclusion, all patients with autoimmune diseases should be screened for the presence of latent TB infection (LTBI) before starting biologic therapy, and periodically monitored for active TB disease, which can be atypical because of immunosuppression.
Keywords: BIOLOGICAL THERAPY, ADALIMUMAB, TUBERCULOSIS, PSORIASIS.

Tumor necrosis factor alpha (TNF-α) inhibitors are widely used for the treatment of chronic immune-mediated inflammatory diseases, such as chronic psoriasis (1). TNF-α is involved in the host defense mechanism against Mycobacterium tuberculosis (MTB), in the granulomatous response preventing the dissemination of infection in the body. The use of TNF-α inhibitors may interfere with the immune response to MTB, thus resulting in an increased risk of reactivation of latent tuberculosis foci and active TB disease development (2). The psoriatic patients receiving TNF-α inhibitors are recognized as a new high risk group for pulmonary or extrap-

ulmonary forms of TB, many of them with poor outcomes (1-5). In Romania, TB control is mandatory, prisons included (6). Screening for LTBI is performed systematically and chemoprophylaxis should be provided to all infected patients before starting anti-TNF-α therapy.

CASE REPORT

A 35-year-old male, construction worker exposed to respirable particles, with a 20-pack year history of smoking was admitted to Constanta Pneumophtysiology Clinic for intermittent cough and fatigue with onset 3 weeks before presentation. Chronic psoriasis was diagnosed 13 months earlier, with good clinical response under biological therapy with adalimumab. Before initiating the anti-TNFα therapy, due to the negative TST, LTBI was not confirmed and chemoprophylaxis treatment was not recommended.

Physical exam revealed no abnormality. Routine biological analyses were normal, HIV screening test was negative, but an erythrocytes sedimentation rate (ESR) of 78 mm/hour and mild blood eosinophilia (400 cells/μL; 7%) were recorded. Chest X-ray revealed a pale tumoral opacity in the left middle lung (fig. 1). Chest computed tomography (CT) showed the presence of a peripheral lung mass lesion with irregular shape, spiculated margins and small cavitation inside, localized in the apical segment of the left upper lobe (LUL) (fig. 2). Enlargement of left hilar, left upper paratracheal and subcarinal lymph nodes was noticed.

TST conversion to positive was a red flag for a possible recent LTBI, but sputum smears were constantly negative for acid fast bacilli (AFB). The fiberoptic bronchoscopy appearance was normal, with bacteriological exam negative for bacteria, fungi and AFB, and bronchial wash cytology negative for neoplasia.

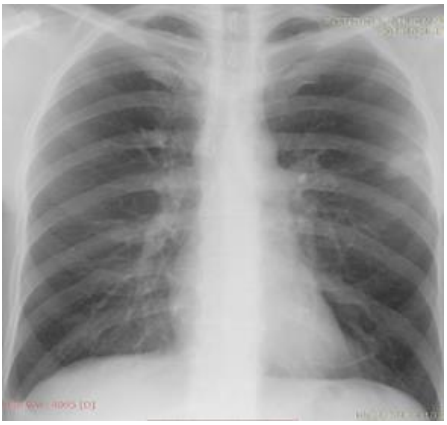

Fig. 1. Chest X-ray showed pale ovalar opacity in the left middle lung.

Fig. 2. Chest CT scan revealed peripheral lung opacity (4.5/5.5 cm), irregular-shaped with spiculated margins and small hyper transparency inside, localized in the apical segment of LUL.

Considering the imaging findings highly suggestive of malignancy, mediastinoscopy with biopsy and histological examination was required. Bioptic samples of paratracheal lymph node revealed joined and isolated non-caseating epithelioid-cell granulomas (fig. 3), suggestive of sarcoidosis.

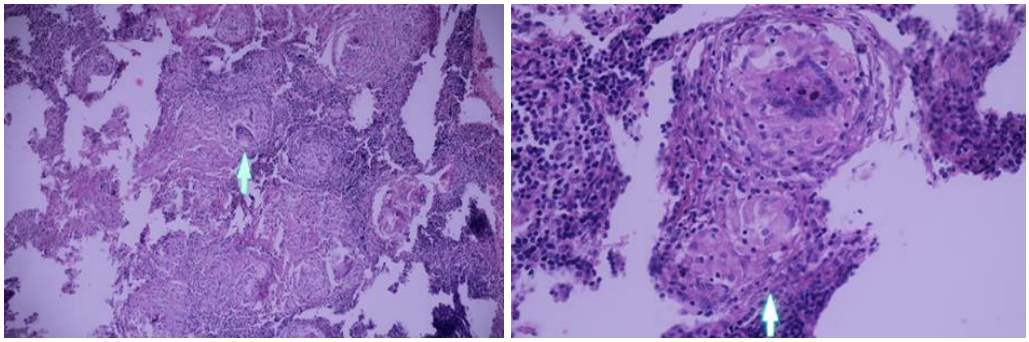

Fig. 3. Mediastinal lymph nodes- Hematoxylin-eosin staining; 10x magnification (left), 40x magnification (right) - non-caseating epithelioid-cell granulomas (arrow)

Due to the discrepancy between CT scan findings and histological result, open lung biopsy was recommended and atypical segmental resection was performed, revealing inflammatory granulomatous lung lesions with caseation necrotic center, histocytes and Langhans-type giant cells, highly suggestive of tuberculoma (fig. 4).

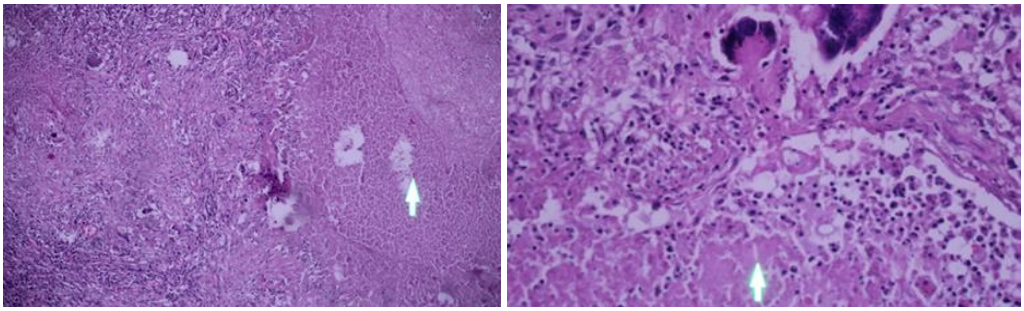

Fig. 4. Tissue Samples of lung biopsy. Hematoxylin-eosin staining - Necrotizing granuloma (left) - 10x magnification - Focal necrosis; arrow: necrosis, arrowhead: epithelioid histiocytes; (right): 40x magnification - arrow: zone of necrosis surrounded by epithelioid histiocytes and Langhans-type giant cells

The presence of necrotizing granuloma with positive AFB staining, along with the 13- month history of anti-TNF-α therapy, as well as TST conversion, together supported a positive diagnosis of TB and the standard first-line regimen of directly observed anti TB therapy was administered for 9 consecutive months, with good clinical, bacteriological and radiological outcomes and complete resorption of lung tuberculoma.

DISCUSSION

Tuberculosis continues to represent a major health problem worldwide, Romania still being one of the high TB burden countries (7, 8). Malnutrition, smoking, alcohol abuse, air pollution, low socio-economic status, along with diverse immunosuppressive conditions are the most common risk factors for TB and for other respiratory disorders (1-4, 9-14).

In this reported case, long term admin-

istration of adalimumab (13 months) for psoriasis increased the TB risk. Recently published data are suggestive for the risk of LTBI progression to TB disease or relapse caused by TNF-α inhibitors. Some monoclonal antibodies, such as adalimumab and infliximab, are associated with a higher risk of TB disease than the soluble TNF-α receptor fusion protein (etanercept) (15). While the monoclonal antibodies bind TNF-α more tightly due to a higher avidity for transmembrane, the soluble receptor may have a higher affinity for the TNF-α molecule (16).

In a smoker, the absence of positive acid-fast smears, the features of lung tumoral mass opacity with associated mediastinal lymphadenopathy were strongly suggestive for lung cancer. Histological pattern of non-caseating epithelioid-cell granulomas in lymph nodes samples collected by mediastinoscopy suggested sarcoidosis. It is well-known the difficulty to differentiate sarcoidosis from TB, especially when caseous necrosis is not seen (17). In our case, positive TST and imaging findings did not support sarcoidosis.

Atypical lung resection was performed revealing tuberculoma. Often, discrepancies are between of lung lesions or interstitial lung disease of unknown etiology required surgical lung biopsy (18). The presence of necrotizing granulomatous inflammation and positive AFB staining supported the diagnosis of TB. Pulmonary tuberculoma may mimic lung cancer or vice versa (19). Usually, in immunosuppressed people, atypical inflammatory tumors (20) or disseminated TB may occur (21, 22). In autoimmune diseases or during prolonged biological therapy, any form of typical or atypical TB can be observed. So, any lung lesion must be systematically screened for TB disease.

CONCLUSIONS

The authors reported this case of false lung cancer tumor in order to emphasize the possible discrepancies between radiological presentation and histological exam in making a positive diagnosis of tuberculosis among patients receiving anti-TNFα agents. Pulmonary tuberculoma may mimic lung cancer. Before initiating treatment with biological agents, negative tuberculin skin test is not enough to exclude TB. Periodic monitoring of these patients is needed.

DIGESTIVE NEUROENDOCRINE NEOPLASMS: COMPUTED TOMOGRAPHY EVALUATION AND PATHOLOGIC CORRELATIONS (Abstract): **Aim:** Our study aims to correlate the enhancement curve (EC) types (obtained after contrast enhanced computed tomography) with tumor grading in case of digestive neuroendocrine neoplasms (NENs). **Material and methods**: Our retrospective analysis included 39 patients with digestive neuroendocrine tumors, evaluated in Iasi with multidetector computed tomography (MDCT) between January 2015 and September 2019, using noncontrast enhanced, arterial and portal venous phases; only 9 patients were evaluated using an intermediate-delayed phase (4 min). Along with the enhancement curve (EC) pattern we evaluated also patient demographics, lesion location, dimensions, homogeneity, presence of calcifications and in case of malignant lesions: local extension, distant and regional lymph nodes metastases. **Results:** The most common location of neuroendocrine neoplasms included in the study was the pancreas (27 cases, 69.23%), followed by the mesentery (6 patients, 15.38%), small bowel (4 patients, 10.25%) and stomach (2 patients, 5.13%). The lesions had the following EC patterns: 27 (69.23%) cases wash-out EC type, 10 cases (25.65%) progressive EC, 2 cases (5.12%) plateau EC. Malignant lesions were found in 9 cases (23.07%) and all had wash-out type EC in the portal venous and intermediate-delayed phases. **Conclusions:** When appropriately combined with other CT features (dimensions, structure, noncontrast CT, arterial, portal venous and intermediate-delayed phases) the enhancement curve types have potential utility in positive diagnosis of digestive neuroendocrine tumors and in differentiating between malignant and benign lesions. **Keywords:** NEUROENDOCRINE TUMORS, WASH-OUT, ENHANCEMENT CURVE.

Neuroendocrine neoplasms (NENs) are proliferative processes that arise from neuroendocrine cells such as enterochromaffin cells or Kulchitsky cells. They can develop throughout the body, the majority occurring in the digestive and respiratory tract. They comprise a large range of neoplasms from the benign to the highly malignant and metastatic ones. In the digestive tract they most commonly occur in the large bowel and in the pancreas. NENs are a heterogeneous group of tumors but they are treated

together because they contain cells witch share common features (have in the cytoplasm secretory granules and produce polypeptides) (1). Historically, the World Health Organization (WHO) classified the neuroendocrine neoplasms differently, according to the site, and this created considerable confusion due to different terminologies and grading criteria in different organs. In 2018 WHO published a new uniform classification for neuroendocrine neoplasms based on a consensus conference held in 2017. NENs are split into neuroendocrine tumors (NETs) and neuroendocrine carcinomas (NECs) based on genetic, clinical, epidemiological, histological and prognostic differences. NETs are graded as G1, G2, G3 on the basis of proliferative activity as assessed by mitotic rate and Ki-67 proliferation index. NEC are considered high grade proliferations and they are split into small cell NECs and large cell NECs. Even though NETs and NECs share neuroendocrine features (demonstrated through synaptophysin and chromogranin A labeling), morphologically they are different. NETs have organoid architecture (nests, cords, ribbons), uniform nuclear features, stippled chromatin and minimal necrosis. NECs have a predominant sheet growth pattern, more atypical nuclear features (often with nucleoli) and usually abundant necrosis (2, 3).

Ultrasound (US), computed tomography (CT), magnetic resonance imaging (MRI) and endoscopic ultrasound were in the past common diagnostic tools for diagnosis of NENs. CT scans is almost always the imaging method of choice for patients with suspicion of NENs, being useful for the evaluation of the primary tumor and staging of NECs (4, 5). Primary tumors and their metastases are hyper vascular and are best seen in the arterial phase of a triple phase CT scan (6). MRI is the best conventional study to detail hepatic metastases in NETs (13). MRI acquisition protocol must include diffusion sequences which help the diagnosis especially in non-hypervascular lesions (6, 7). Positron emission tomography (PET) imaging with fluorine-18 fluorodeoxyglucose (FDG) and somatostatin receptor imaging combined with PET may be valuable to image some neuroendocrine tumors (8).

MATERIAL AND METHODS

Our retrospective analysis included 39 patients with abdominal neuroendocrine neoplasms, evaluated at the Radiology Department, "Sf. Spiridon" County Clinical Emergency Hospital from Iasi, between January 2015 and September 2019 with multidetector computed tomography (MDCT) and we correlated the patterns with the histopathological results. The inclusion criteria were age over 18 years old; neuroendocrine neoplasm with intervention and biopsy; availability of preoperatory CT scan with or without IV contrast agent in our institution from 2015-2019, while the exclusion criteria were as follows: pregnancy or history of another malignancy.

We performed MDCT examinations with noncontrast enhanced, arterial and portal venous phases for all patients and only 9 patients (the ones with malignant lesions) were evaluated using an intermediate-delayed phase (4 min). Abdominal MDCT examinations were performed using Siemens Somatom Emotion 16 equipment, with the following protocol:

- patients were asked to sign the informed consent for contrast enhanced CT examinations;

- an intravenous line was placed; the patient was scanned in supine position;
- a scout view for the abdomen was performed;
- noncontrast enhanced phase for the abdomen al pelvis was done;
- we injected intravenously iodinated contrast media (370 mg iodine/mL), at flow rate of 4 mL/s);
- arterial (at 15 seconds), portal venous (at 60-70 seconds) and intermediate-delayed phases (at 4 minutes after intravenous contrast medium injection) were performed.

We measured the tumoral attenuation values (CT densities) on noncontrast enhanced, arterial, portal venous and intermediate-delayed phases and we draw with this values enhancement curves (EC) for each tumor. We considered the following patterns of EC:

- a washout EC type when the density increased in the arterial phase and decreased with more than 40% in the portal venous and intermediate –delayed phases;
- a progressive EC when the density increased continuously in arterial and portal venous phases;
- a plateau EC when the density had variations with less than 10% between the CT phases.

Arterial and venous relative tumor enhancement ratio (RTER) was obtained by dividing tumor densities: arterial or venous postcontrast by noncontrast enhanced.

Tumor tissue sections were obtained for histopathologic and immunohistochemical studies. The tissue samples were fixed in 10% neutral buffered formalin before being dehydrated and paraffin embedded. For histopathologic evaluation, 5-µm sections of formalin-fixed, paraffin-embedded (FFPE) were stained by a standard method with hematoxylin and eosin (HE) with a Leica Autostainer XL (Leica Biosystems, GmbH, Wetzlar, Germany). Immunohistochemical (IHC) staining were performed using the Roche-Ventana BenchMark XT automatic immunostainer (CC1 standard; ULTRA View DAB Detection Kit) following the manufacturer's recommendations (Ventana Medical Systems, Tucson, AZ, USA). Monoclonal ready to use antibodies to the following antigens were used: synaptophysin (rabbit monoclonal, clone SP11 Roche Tissue Diagnostics) chromogranin (mouse monoclonal, clone LK2H10, Roche Tissue Diagnostics) CD56 (mouse monoclonal, clone 123C3, Roche Tissue Diagnostics), Ki-67 (rabbit monoclonal, clone 30-9, Roche Tissue Diagnostics).

RESULTS

We reviewed 39 patients with histologically confirmed NENs (24 females and 15 males - female to male ratio = 1.6:1), with 32-87 years age range (28-71.79% patients in the 6th, 7th and 8th decade) (fig. 1). Each study was initially independently reviewed by two expert radiologists (IJ and MU, each with > 20 years of experience) by using a dedicated radiology imaging software (Siemens Syngo Multimodality Workplace CT Workstation, Siemens Healthcare, Erlangen, Germany). The images were set to corresponding standard window center and width values for evaluation of lung, soft tissue, and bone. For cases with discordant results, a consensus reading with arbitration by a third radiologist was carried out, and the observers were asked to make the final assessment. The intraclass correlation coefficient (ICC) was used to determine interrater and intrarater reproducibility; ICC greater than 0.75 indicated strong agreement and ICC of 0.4-0.75 indicated average agree-

ment. A *p* value of less than .05 was considered to indicate statistical significance. Interrater agreement for the three readers was average-to-strong for tumor location (ICC, 0.88), and the intrarater agreement was strong (ICC, 0.94).

The most common location of neuroendocrine neoplasms included in the study was the pancreas (27 cases, 69.23%), followed by the mesentery (6 patients, 15.38%), small bowel (4 patients, 10.25%) and stomach (2 patients, 5.13%) (fig.2, 3).

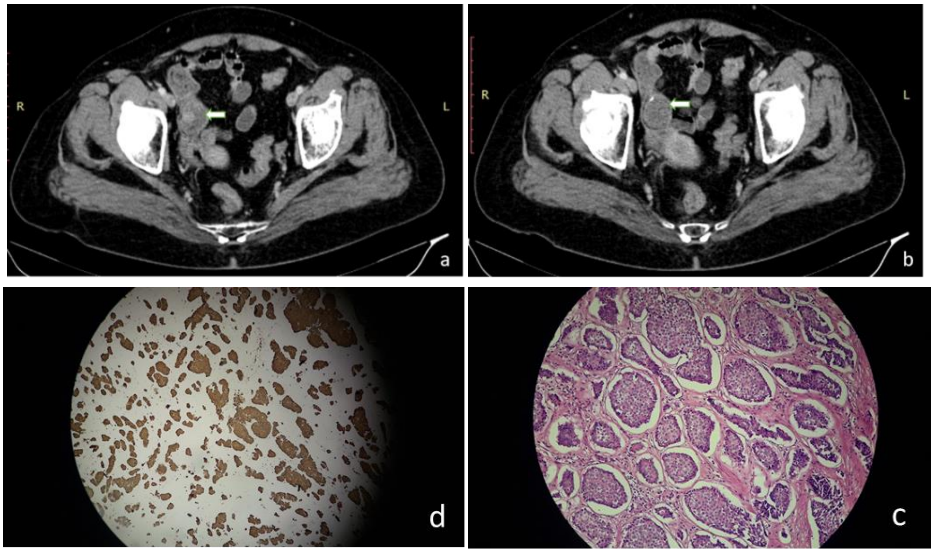

Fig. 1. Small bowel NEN - a, b - contrast enhanced CT, portal venous phase – round, well defined, with inhomogeneous contrast enhancement ileal loop NEN; c – HE staining - the tumor has solid architecture or nested distribution; the cells are monotonous, with coarse salt and pepper chromatin; cytoplasm is abundant, eosinophilic and granular;
d. IHC staining with monoclonal antibody against chromogranin demonstrate diffuse and intense staining, a characteristic feature for neuroendocrine neoplasms.

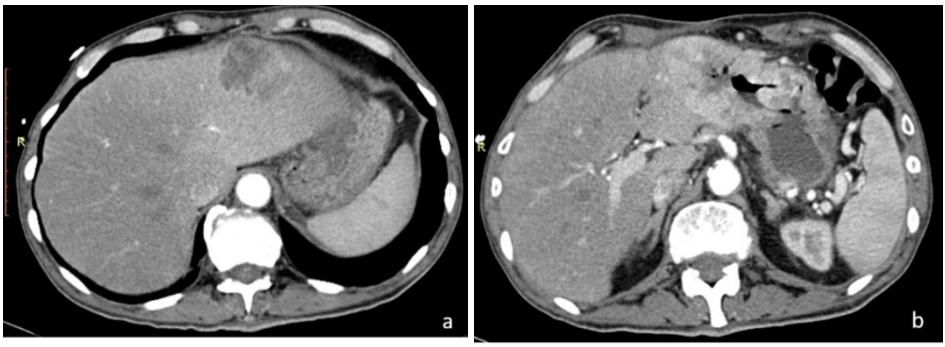

Fig. 2. Stomach NEC - contrast enhanced CT, arterial phase – liver metastasis - round, irregular, poorly defined lesion, with peripheral contrast enhancement (a), gastric mass with intense, inhomogeneous contrast medium uptake (b)

The attenuation values measurements on contrast enhanced MDCT demonstrated that 33 (84.61%) lesions were hypervascular, very well visualized in the arterial phase, 6 (15.39%) tumors were hypovascular, with a medium and low contrast enhancement in portal venous phase. We found the following EC patterns: in 27 (69.23%) cases a wash-out EC type, 10 tumors (25.65%) had a progressive EC and 2 (5.12%) a plateau EC. NECs were found in 9 cases (23.07%) and all had wash-out EC type in the portal venous and intermediate-delayed phases.

MDCT image analysis was focused also on arterial and venous relative tumor enhancement ratio (RTER). The arterial RTER was 2.73 ± 3.5 and the venous RTER was 2.39 ± 4.2 ($p < 0.05$). CT attenuation values and contrast ratios of pancreatic neuroendocrine tumors in the arterial and venous phases were higher than those of mesenteric and small bowel ($p < 0.05$).

Correlating the tumor dimensions and structure with the pathologic results we found:

- 25 (64.10%) tumors had dimensions between 1.5 and 2.5 cm and were homogeneous, and were graded as G1 and G2;

- 14 lesions were larger than 2.5 cm and had an inhomogeneous structure on nonenhanced and contrast enhanced phases; 5(12.82%) lesions were graded as G1, and G2, 9 (23.07%) tumors had G3 grade.

Only 5 (12.82%) large masses had linear, nodular and polymorphic calcifications.

The metastatic potential of neuroendocrine tumors and the correlation with the tumor grading was determined by studying the perilesional extension, regional lymph node involvement and distant metastases (tab. I).

TABLE I

The metastatic potential of neuroendocrine tumors – correlation with the tumor grading

Tumor grading	Perilesional extension		Lymph node metastases		Distant metastases	
	Absent	Present	Absent	Present	Absent	Present
G1, G2 (30 patients)	70% (21/30)	30% (9/30)	83.33% (25/30)	16.67 % (5/30)	86.67% (26/30)	13.33% (4/30)
G3 (9 patients)	33.33% (3/9)	66.67 % (6/9)	55.55% (5/9)	44.45 % (4/9)	44.45% (4/9)	55.55% (5 / 9)

DISCUSSION

There are several possible reasons for the low number of cases included in this study. First, neuroendocrine tumors have a low incidence with a reported value of 5–7 per 100,000 population per year and estimated prevalence of 35 per 100,000 (9). Second, the majority of tumors are nonfunctional and consequently the presentation may be incidental (10). CT scans are often the initial imaging study for a patient presenting with signs or symptoms suggestive of a NET, but in primary NETs, the average sensitivity of a CT scan is 73% (11). CT scans have even better sensitivity in detecting NET metastases, as they demonstrate 80% sensitivity for hepatic metastases (11, 12) and 75% sensitivity for extrahepatic metastases (11).

In our study we found a female to male ratio of 1.6 : 1, compared with the literature which states that neuroendocrine tumors

appear mostly in case of men. Most of the patients were old: 28 (71.79%) of them were between 61 and 87 years old, confirming the literature data which sustained that older person have increased risk of developing a neuroendocrine tumor (13, 14).

The most common location of neuroendocrine tumors included in the study was the pancreas followed by the mesentery and small bowel as compared with the literature were these tumors are mostly located in the small bowel (13, 14).

The density measurements on arterial and venous phases demonstrated that 33 (84.61%) lesions had a high uptake in the arterial phase and 6 (15.39%) tumors had a medium and low contrast enhancement in portal venous phase; this findings were confirmed by many authors who found the same heterogeneity of lesions: benign lesions were hyper vascular, small masses in arterial phase, isodense during portal phase and malignant tumors had heterogeneous enhancement (4, 11).

The study of enhancement curve (EC) patterns demonstrated that 27 lesions had a wash-out EC type, meaning that 18 (60%) benign and 9 (100%) malignant tumors had wash-out EC type.

MDCT image analysis was focused also on arterial and venous relative tumor enhancement ratio (RTER). The arterial RTER was 2.73 ± 3.5 and the venous RTER was 2.39 ± 4.2 ($p < 0.05$). CT attenuation values and contrast ratios of pancreatic neuroendocrine tumors in the arterial and venous phases were higher than those of mesenteric and small bowel ($p < 0.05$).

Correlating the tumor dimensions, structure and the presence of calcifications we found that:

- most of G1 and G2 lesions (25 of 30 – 83.33%) were small with homogeneous appearance;
- G3 tumors were all large, with heterogeneous enhancement and 5 (55.55%) of them had calcifications.

Our results confirmed the literature data concerning of the metastatic potential of neuroendocrine tumors: most tumors with G1 and G2 grades have no perilesional extension (70%), no lymph node involvement (83.33%) and distant metastases (86.67%). On the other hand, most of G3 tumors have perilesional extension (66.67%) and distant metastases (55.55%) but lymph node involvement have been demonstrated only in 44.45% of cases.

CONCLUSIONS

The enhancement curve types provide some opportunity for lesion differentiation between malignant and benign. The diagnostic performance can be improved by appropriate combination with other quantitative CT parameters like lesion dimension and structure, noncontrast and enhanced CT with intravenous contrast material (arterial, portal venous and intermediate-delayed phases).

THE ROLE OF LYMPHOCYTE-TO-MONOCYTE RATIO AND PLATELET-TO-LYMPHOCYTE RATIO REPORTS AS A PREDICTIVE FACTOR FOR THE OCCURRENCE OF INTESTINAL NECROSIS IN COMPLICATED INCISIONAL HERNIAS (Abstract): The current study **aims** to identify the role of lymphocyte-to-monocyte ratio (LMR) and platelet-to-lymphocyte ratio (PLR) reports as a predictive factor for the occurrence of intestinal necrosis in patients with incisional hernias and the cutoff values for LMR and PLR. **Material and methods:** We performed a 4-year retrospective study that included 168 patients in whom we determined MRL and PLR reports. **Results:** From the statistical analysis we noticed that the cutoff value for LMR as a predictive factor in the case of intestinal resections is 2.716 (sensitivity of 54.2% and specificity of 88.4%). For PLT the cutoff level is 124, below this threshold the specificity decreases and the sensitivity increases. Comparing LMR and PLR, the ratio of lymphocytes to monocytes is the most sensitive and specific. AUC=0.712 (C.I. 95% = 0.638 to 0.779), p value of 0.0029. **Conclusions:** Elevated LMR levels are associated with the occurrence of bowel necrosis in strangled or incarcerated incisional hernias. **Keywords:** INCISIONAL HERNIA, LYMPHOCYTE-TO-MONOCYTE RATIO, PLATELET-TO-LYMPHOCYTE RATIO.

The treatment of incisional hernia is one of the most common pathologies faced by general surgeons. Between 5 and 30 patients out of 100 operated cases will develop an incisional hernia in the first 12 months (1). There are a multitude of surgical techniques, nonperfect, that must be adapted to all patients and their comorbidities. We often encounter obesity, advanced age, chronic diseases like diabetes or chronic obliterative bronchopneumonia (COPD) as associated pathology (2, 3, 4).

An abdominal wall defect, with or without the local presence of a bulging tumor during intra-abdominal pressure increasing maneuvers, clinically or paraclinically detectable in the first year after surgery is a common definition of incisional hernia. Incisional hernias appear as a complication of a laparotomy, especially if the postoperative wound had a septic evolution. The patient presents to the surgeon at the time of clinical manifestations. Because not every incisional hernia has an operative indication, the physician must consider several major elements: pain, bowel movements disorders, manifestations that reduce the quality of life and the risk of complications. Incarceration and strangulation are the events that require emergency surgery, due to the possibility of intestinal necrosis (5).

The current trends are to use positive criteria for systemic inflammatory response syndrome (SIRS) as a potential "alarm signal", both preoperatively and postoperatively. The magnitude of preoperative SIRS shows the urgency of applying treatment and postoperative prolongation is associated with organ dysfunction and the occurrence of postoperative complications (6,7). A simple method of measuring SIRS is to calculate the ratios of serum lymphocytes (LYM), monocytes (MON) and platelets (PLT) - LMR and PLR (8). The current study aims to identify the role of LMR and PLR reports as a predictive factor for the occurrence of intestinal necrosis in patients with incisional hernias and the cutoff values for LMR and PLR.

MATERIAL AND METHODS

We performed a 4-year retrospective study in the General Surgery Department of the Onești "Saint Hierarch Dr. Luca" Municipal Hospital. Thus, between January 1, 2016 and December 31, 2019, we analyzed the clinical records and the hospital's own computer system - InfoWorld, from where we selected 168 patients who underwent surgery for incisional hernia. We excluded from the study patients with incisional hernias who have other conditions that may lead to systemic inflammatory syndrome, as well as those who needed to perform a colon resection.

When admitting patients to the hospital in emergency conditions or by appointment, they were collected usual laboratory analyzes (serum glucose, complete blood count, exploration of liver function, exploration of renal function, coagulation, blood compatibility). We turned our attention to the complete blood count (CBC), from where we tracked the serum values of LYM, MON, neutrophils (NEU), PLT and white blood cells - WBC. With these values we calculated the ratios between lymphocytes and monocytes (LMR), as well as between platelets and lymphocytes (PLR).

RESULTS

From the analysis of the collected data, we observed a uniform distribution of the number of patients for the years included in the study (tab. I). Regarding the age of the patients in our observational study, it ranged from 19 to 89 years.

From the descriptive analysis of the data, we noticed that the gender division of the cases counted 38 men (approximately 23%) and 130 women (78%). Regarding the type of hospitalization, we obtained a percentage of emergency admission of 57%, which represents 96 patients. The number of those admitted to the surgery department by appointment was lower, of about 43%.

TABLE I

Distribution by year of the number of patients

		Frequency	Percent	Valid Percent
Valid	2016	46	27.38	27.38
	2017	39	23.21	23.21
	2018	56	33.33	33.33
	2019	27	16.07	16.07
	Total	168	100.0	100.0

At the time of admission, all patients underwent an initial surgical consultation to determine whether surgery was required or could be delayed. The physician's decision was the result of a combination of local clinical examination, medical history, and the patient's biological condition. Thus, we observed that the surgery was performed in emergency in 55 cases, and in 113 cases, the surgery was performed under scheduled conditions (tab. II).

TABLE II

Time of surgery

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Acute	55	32.74	32.74	32.74
	Chronic	113	67.26	67.26	100.0
	Total	168	100.0	100.0	

In 16.07% of cases, during the surgery due to intestinal viability disorders, it was necessary to practice a small bowel resection (tab. III). All surgeries were performed in the classic manner with lateral-to-lateral anastomoses as well as intra-abdominal and subcutaneous drainage. Also, in 41% of cases, for the restoration of the abdominal wall it was necessary to use prosthetic materials - polypropylene mesh (tab. IV).

TABLE III

The need for intestinal resections

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	YES	27	16.07	16.07	16.07
	NO	141	83.93	83.93	100.0
	Total	168	100.0	100.0	

TABLE IV

The use of prosthetic materials in abdominal wall reconstruction

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	YES	69	41.07	41.07	41.07
	NO	99	58.93	58.93	100.0
	Total	168	100.0	100.0	

The descriptive statistics of the two LMR and PLR reports depending on the time of surgery show that the variables do not have a Gaussian distribution, and the median of LMR has the value of 4.57 (tab. V).

TABLE V

LMR and PLT analysis depending on the time of surgery

Acute / Chronic INTERVENTION		LYM/MON	PLT/LYM
Acute	Mean	4.261418	154.904105
	Std. Deviation	3.2908009	123.4327013
	Median	3.407800	128.571400
	Minimum	.3842	23.6907
	Maximum	20.0000	905.6818
Chronic	Mean	5.136754	129.837650
	Std. Deviation	2.3282385	59.4598913
	Median	4.848400	119.433100
	Minimum	.6233	38.7417
	Maximum	20.7272	510.4166
Total	Mean	4.843259	138.242285
	Std. Deviation	2.7115718	86.7893866
	Median	4.575400	122.861100
	Minimum	.3842	23.6907
	Maximum	20.7272	905.6818

From the analysis of inferential statistics, by applying the Mann-Whitney test, we noticed that the LMR value was statistically correlated with the need to perform an intestinal resection, with a p value below 0.05 (tab. VI).

TABLE VI

Statistical significance of LMR

Intestinal Resection	LYM/MON	PLT/LYM
Mann-Whitney U	1008.000	1143.000
Wilcoxon W	1308.000	11874.000
Z	-3.330	-2.725
P value	0.001	0.006

In the case of the LMR report, in patients with intestinal resection, the established cutoff level is 2.716, below this threshold the sensitivity decreases and the specificity increases (fig. 1) and for PLR the established cutoff is 124 (fig. 2).

The values of LMR report above 2.716 correlate with the existence of intestinal necrosis in patients with incisional hernias. Comparing LMR and PLR reports, the ratio of lymphocytes to monocytes is the most sensitive and specific (tab. VII).

In the case of PLR report, we established the existence of a cutoff value of 124 which correlates with the existence of intestinal necrosis in the case of the studied patients (fig. 2).

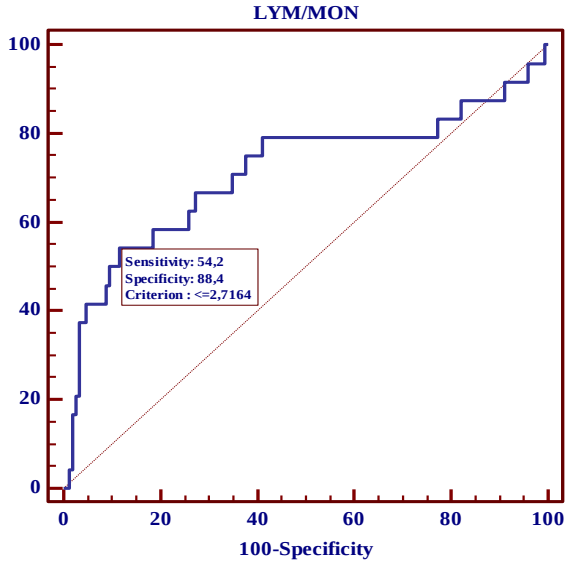

Fig. 1. Sensitivity and specificity of LMR in patients undergoing bowel resections

TABLE VII

Comparison of LMR and PLR reports

	AUC	SE [a]	95% CI [b]
LYM_MON	0.712	0.0713	0.638 to 0.779
PLT_LYM	0.674	0.0601	0.598 to 0.744

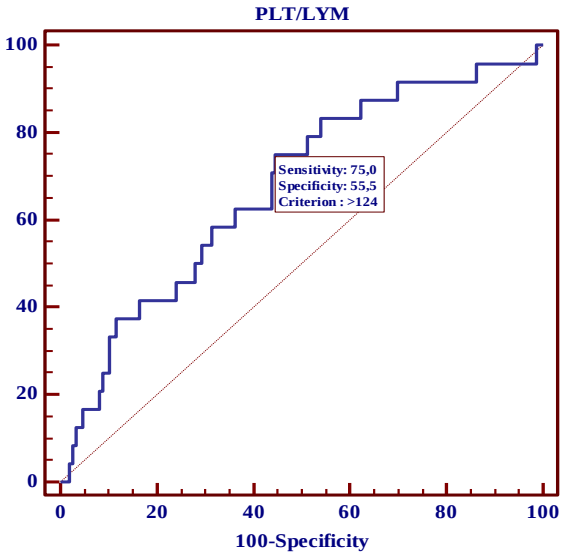

Fig. 2. Sensitivity and specificity in the case of PLR

DISCUSSION

Incisional hernias are a topical public health issue. Currently there is an upward trend to use the endoscopic or laparoscopic approach in the treatment of abdominal pathologies, which reduces in number and difficulty the surgical operations dedicated to the abdominal wall defects. As a result, incisional hernias remain the prerogative of patients debilitated by severe, long-lasting comorbidities, elderly, in whom the emergency surgical indication becomes the rule. The main risk factors associated with surgery are diabetes and chronic obstructive pulmonary disease (9, 10).

Complications of incisional hernias - incarceration and strangulation, determine the initiation of the systemic inflammatory process. The quantification of the patient's inflammatory status is based on the criteria of the systemic inflammatory response syndrome (11-13). It is well known that the migration of NEU into the affected tissues is the first response to the onset of the cytokine storm. The local inflammatory process involves the participation of many serum cells: WBC, NEU, LYM, MON, PLT. Thus, the variation of the number of serum cells may indicate the progression of the local inflammatory syndrome, as well as the appearance of local and general complications (14).

In some patients with incisional hernia, the intestinal loops may suffer irreversible damage leading to their necrosis. Local examination of patients with complicated incisional hernias is not sufficient to determine the viability of bowel loops. Necrosis of the intestinal segment causes peritonitis and septic shock. In this situation the patient's life depends on the emergency surgery (15, 16).

Many studies have sought to establish a correlation between changes in the patient's serum cellularity and inflammatory status secondary to intestinal necrosis. In this sense, the importance of the ratios between the serum values of NEU, LYM, MON and PLT – neutrophil-to-lymphocyte ratio (NLR), lymphocyte-to-monocyte ratio (LMR) and platelet-to-lymphocyte ratio (PLR) was investigated (17-20). It has been observed that LMR and PLT can be used as biological markers with predictive potential in determining the extent of the inflammatory response, and therefore in the occurrence of intestinal necrosis (21,22).

In our study from the data analysis, we note that the median of LMR in patients with intestinal resection is 3.956, and in the group without resection is 4.989. From the statistical analysis we noticed that the cut-off value for LMR as a predictive factor in the case of intestinal resections is 2.716 (sensitivity of 54.2% and specificity of 88.4%). For PLT the cutoff level is 124, below this threshold the specificity decreases and the sensitivity increases. We consider that monitoring the serum levels of WBC, LYM, NEU, PLT and MON is easy to do and does not require additional special equipment.

One of the main limitations of our study is the small number of patients included in the study. Although the results are promising, there is still a need for studies on larger groups of patients, randomized and prospective.

CONCLUSIONS

Elevated Lymphocyte-To-Monocyte ratio levels are associated with the occurrence of bowel loop necrosis in incarcerated and strangled incisional hernias.

NEWS

ANSWERING KEY QUESTIONS ABOUT COVID-19 VACCINES

In the US, 4 vaccine candidates are in phase 3 clinical trials with initial results expected soon. If studies succeed, 1 or more vaccines may become available within a few months. The article focuses on common questions people are likely to ask about COVID-19 vaccines. ***How Much Does a Vaccine Reduce the Risk of COVID-19 and Its Complications?*** The US Food and Drug Administration (FDA) guidance set as an expectation for licensure that a COVID-19 vaccine would prevent disease or decrease its severity in at least 50% of people who are vaccinated. The study showed a 50% reduction in illness, but the confidence interval for the efficacy estimate might be 30% to 80%, which means efficacy may be as low as 30% or as high as 80%. Also, a vaccine reduces not only mild but also more severe disease, as well as hospitalizations and deaths. ***Will the Vaccine Be Effective for All Patients?*** COVID-19 is more common and severe among individuals often underrepresented in clinical trials, including older individuals, people with chronic illnesses, and persons in racial/ethnic minority populations. When results become available, it will be important to evaluate the characteristics of people included in the trial and determine whether they are similar to patients seen in the practice setting because a given vaccine may be more appropriate for some patients than others. ***Is a Vaccine Licensed or Provided Under an Emergency Use Authorization?*** FDA has a long track record of licensing vaccines that have protected individuals against diseases like measles, polio, and pneumonia and has stated it will apply its usual high standards to COVID-19 vaccines. ***Will All COVID- 19 Vaccines Be the Same?*** Different vaccines are likely to perform and be used differently and clinicians will need to be aware of any differences between vaccines including dose numbers and schedules, as well as safety and efficacy because some vaccines may be preferred for certain populations. ***Can Vaccinated People Stop Worrying About COVID-19?*** While a vaccine will help protect individual patients and those around them, a large proportion of the population must be immunized and protected before transmission is substantially reduced. No vaccine will be 100% effective and a vaccine that protects against developing clinical illness may not prevent transmission to others. Even after vaccines become available, SARS-CoV-2 will be a continuing concern. Effective public health measures, such as social distancing, and wearing masks, will be needed for at least several more months, and potentially longer. (Goodman JL, Grabenstein JD, Braun MM. Answering Key Questions About COVID-19 Vaccines. *JAMA*. Published online October 16, 2020. doi:10.1001/jama.2020.20590).

OPHTHALMIC PATHOLOGY TREATED DURING COVID-19 AT THE OPHTHALMOLOGY CLINIC OF "SF. SPIRIDON" COUNTY CLINICAL EMERGENCY HOSPITAL IN IAŞI, ROMANIA

OPHTHALMIC PATHOLOGY TREATED DURING COVID-19 AT THE OPHTHALMOLOGY CLINIC OF "SF. SPIRIDON" COUNTY CLINICAL EMERGENCY HOSPITAL IN IAŞI, ROMANIA (Abstract): Within the current epidemiological context and due to the increased risk of infectivity, this article focuses on the practical activity of "Sf. Spiridon" Ophthalmology Clinic in Iaşi, during the emergency period (March 16th -May 16th, 2020), the evaluated ocular pathology and the approached strategy from the point of view of medical and surgical vision. **Material and methods:** As an Emergency Hospital and Tertiary Center of Moldova, Romania "Sf. Spiridon" Hospital in Iaşi was the only hospital in the region that dealt with all the urgent ophthalmological pathology during COVID-19. The clinic worked due to the established protocol, the patient's circuit was changed, with the buffer zone for the suspicious COVID-19 patient, where the patient was hospitalized until the negative PCR result. All patients having a negative PCR test benefited from both medical and / or surgical treatment depending on the type of ocular pathology. **Results:** 619 patients were examined in the emergency room, of which 61 patients were hospitalized in Clinic I Ophthalmology, "Sf. Spiridon" Hospital in Iaşi, between March 16 and May 16, 2020. Most patients (59%) came from the neighboring counties (Suceava, Vaslui, Piatra Neamţ, Bacău) the rest being from Iaşi (41%). The age varied from 2 to 87 years, the average age being 51.72 ± 22.16. Most frequently, patients were hospitalized with retinal detachment (29.5%), trauma (24.6%) and corneal sclerosis (13.1%), most cases being surgical. The average length of stay was 6.3 days. The average time of surgery stages was 45 minutes. The condition at discharge was in 60% of cases improved and 30% cured. All patients tested negative for COVID-19 PCR. Visual acuity and IOP showed slightly higher / lower changes at discharge than at the time of admission. Depending on the diagnosis, the average stay for the patients with retinal detachment was about 4 days, while for patients with glaucoma (13 days) or ulcer corneal (12 days), the long-term hospitalization exceeded 12 days. The multivariate analysis showed that about 10% of the number of days spent in hospital (dependent variable) can be explained by the diagnosis of hospitalization and the type of intervention. Correlated with the status of discharge, the number of days spent in hospital did not differ significantly. **Conclusions:** Most of the ophthalmological activity during the pandemic was surgical, due to the large number of trauma cases from neighboring counties, being the only non-COVID-19 hospital in the North-eastern region of Romania. Complying with the protocol suggested by

the American Academy of Ophthalmology for protection in the case of ophthalmic surgery allows standard eye care and safe surgery to maintain a sustainable application. **Keywords**: COVID-19, SARS-CoV-2, SURGICAL MANAGEMENT, MEDICAL MANAGEMENT.

SARS-CoV-2, which causes COVID-19, is a virus discovered in December 2019 in Wuhan, China. In the immediate aftermath of the rapid spread, the World Health Organization (WHO) declares it a public health emergency, of international concern on 30 January 2020 and a pandemic on 11 March 2020. The initial cases of zoonotic transmission from bats (1) have evolved into a human-to-human transmission through drops, vomiting (2), feces (3), and tears since then. Studies show that the detection of SARS-CoV-2 in tears and conjunctival secretions shows an increased risk of transmission in the field of ophthalmology, which determines the creation of special measures for medical and surgical procedures. Within this epidemiological context, the AAO (American Academy of Ophthalmology) on March 18 provides a series of recommendations for ophthalmologists in solving urgent cases during the COVID-19 emergency period (4). The emergency period was established in Romania in March, the ophthalmology clinic operating on the basis of a protocol involving patient reception and testing circuits in the buffer zone, until the COVID-19 test.

MATERIAL AND METHODS

The ophthalmology clinic within St. Spiridon Hospital in Iaşi is the tertiary center in Moldova, Romania, being the only hospital in the region was the only hospital in the region that dealt with all the urgent ophthalmological pathology during COVID-19. The clinic worked due to the established protocol, the patient's circuit was changed, with the buffer zone for the suspicious COVID-19 patient, where the patient was hospitalized until the negative PCR result. Subsequently, the patient with negative PCR test received both medical and / or surgical treatment depending on the eye pathology. Strict infection control measures have been put in place to minimize the spread of COVID-19 infection. These include personal protective equipment (PPE) for healthcare workers and routine cleaning of "high-touch" surfaces. During the emergency period, both the outpatient activity of non-urgent cases or controls was restricted. The patients were monitored as follows: their temperature was taken at the tent in the Hospital Triage, and they filled in a questionnaire on the main symptoms of COVID-19 infection. Certain surgical cases that underwent postponement (elective, scheduled cases): cataract surgery, strabismus, oculoplastic, orbital surgery were postponed for safety reasons. Urgent cases coming from the emergency unit were accepted at the hospital: corneal wounds, strong contusive traumas, recent retinal detachment, intraocular foreign bodies, advanced drug-decompensate glaucoma, and various severe eye injuries in children. All cases presented in the outpatient clinic that were not urgent were rescheduled, and all patients who were scheduled in the emergency period were called and will be rescheduled outside this period. Both medical staff and nurses were equipped according to the protocol suggested by the WHO (World Health Organization), the Ministry of

Health and the AAO (American Academy of Ophthalmology). It consisted of a surgical face mask, FFP2, FFP3, disposable gloves, goggles, a visor, and a special protective gown. The COVID-19 + suspicious cases from the emergency reception unit were evaluated in the special room and with complete special protection equipment (coveralls, mask, gloves, boots, visor, glasses). There were particular cases when in addition to the evaluation the fully equipped doctor performed a series of maneuvers and surgeries in the special room: removal of foreign bodies from the cornea, suturing of eyelid and corneal wounds due to the increased risk of exposure depending on the type of intervention and its duration.

Statistical processing. The database was built in *EXCEL* and was statistically processed with the *SPSS 18.0.* These represent software for statistical and graphical data analysis, with an interface that helps the user to solve any need for processing experimental data. The statistical analysis of the data was performed with *SPSS 18.0* and consisted in applying the following tests: *ANOVA, Student t-test, F-test* etc.

RESULTS

619 patients were examined in the emergency room, of which 61 patients were hospitalized in Clinic I Ophthalmology, St. Spiridon Hospital in Iaşi, between March 16th and May 16th, 2020. Most patients (59%) came from the neighboring counties the rest being from Iaşi (41%) (fig. 1).

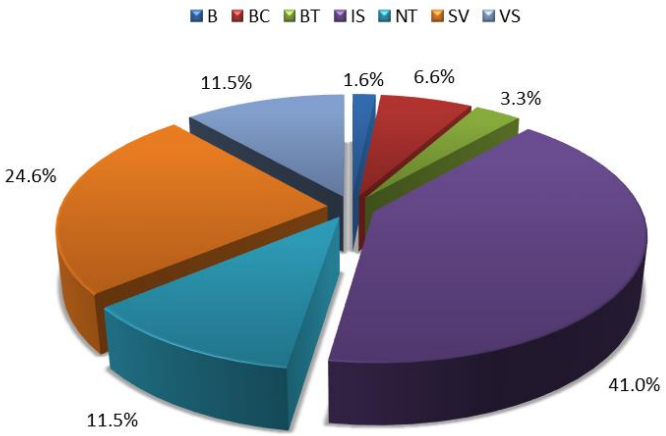

Fig. 1. Distribution of subjects according to the county of origin [of Iași (41%), Suceava (24.6%), Neamț (11.5%) and Vaslui (11.5%) counties]

Age ranged from 2 to 87 years; the mean level 51.72 ± 22.16 years close to the median value (55 years). Most frequently, patients were hospitalized with retinal detachment (29.5%), trauma (24.6%) and corneal sclerosis (13.1%); most cases being surgical (fig. 2). The lowest mean age level was observed in the patient with preseptal cellulitis and in patients with corneal burns, while patients with dislocated crystalline mass or shingles were over 76 years (p = 0.02). The

distribution by sex highlighted the predominance of male cases, except for glaucoma where all cases were female. The average length of stay was 6.15 days (fig. 3). The average time of surgery stages was 45 minutes. The condition at discharge was in 60% of cases improved and 30% cured Postoperative complications were identified in 7 of 61 patients (11.5%) especially the increase in IOP in 3 of 7 cases.

Of the total study group, COVID-19 testing was performed in 65.6% of patients, the results being negative in all cases. The test was not performed in all patients, because, on the one hand, they came with the test performed in another diagnostic center and, on the other hand, they received emergency surgical treatment, stayed in the buffer zone, and then were discharged. Of the total cases, 82% required surgery.

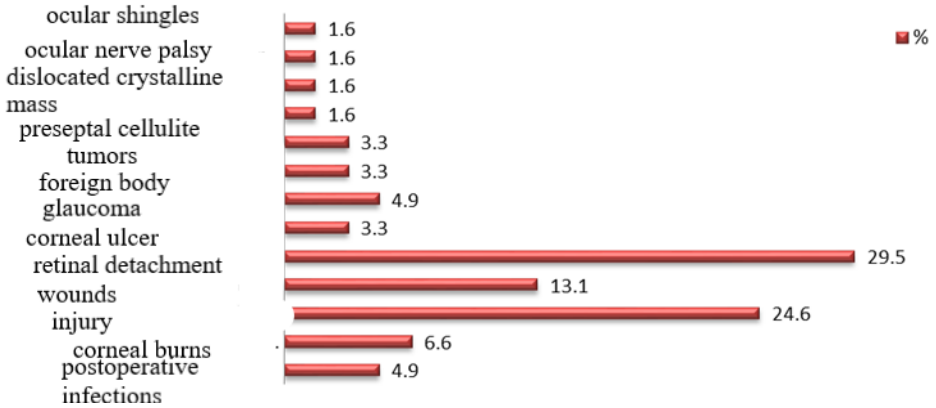

Fig. 2. Distribution of cases according to the diagnosis at admission

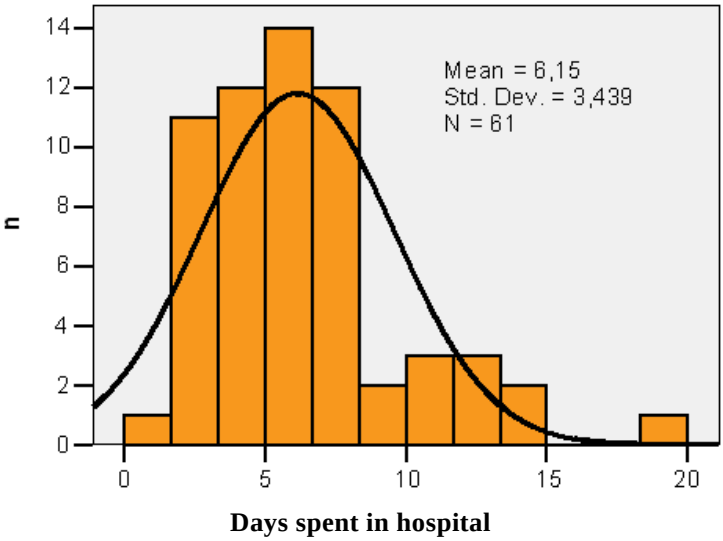

Fig. 3. Histogram of the days spent in hospital

Visual acuity in the affected eye at admission varied within the range of 0-1, with a slightly higher mean level in patients with a negative COVID-19 test result (0.181 *vs.* 0.178; p = 0.969). In patients with a negative COVID-19 test at discharge, the visual acuity slightly increased compared to the time of admission, but the difference was not statistically significant (0.181 ± 0.333 *vs.* 0.256 ± 0.332; p = 0.08) (fig. 4).

IOP in the affected eye at admission varied in the range of 4-56, registering a slightly lower average level in patients with a negative COVID-19 test result (12.90 *vs.* 13.24; p = 0.907). In patients with a negative COVID-19 test at discharge, intraocular pressure ranged from 3 to 31, with a slightly higher mean level than in non-tested patients (12.75 *vs.* 11.10; p = 0.298). In patients with a negative COVID-19 test at discharge, the IOP slightly decreased compared to the time of admission, but the difference was not statistically significant (12.90 ± 9.95 *vs.* 12.75 ± 6.17; p = 0.587) (fig. 5).

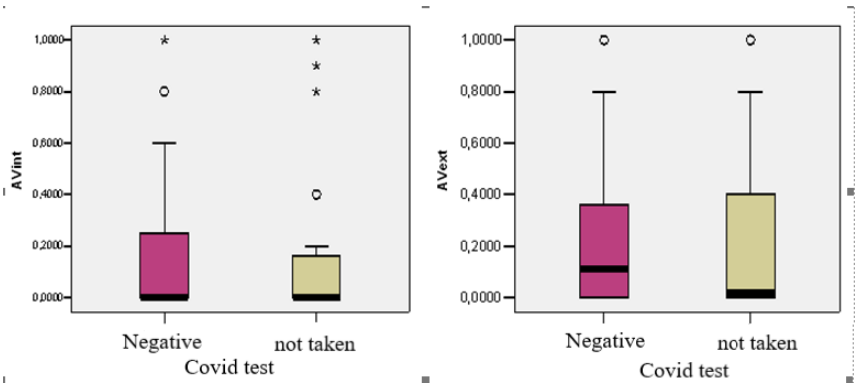

Fig. 4. Average values of visual acuity during hospitalization depending on the COVID-19 test result

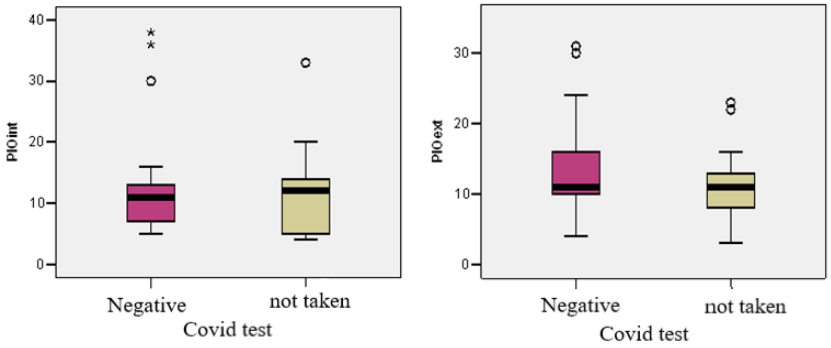

Fig. 5. Average IOP values during hospitalization depending on the COVID-19 test result

The number of days spent in hospital was significantly lower in patients with PPV (pars plana vitrectomy) (4.15 ± 1.09 days) compared to patients without surgery (7.0 ± 3.32) (p = 0.027) (fig. 6).

Depending on the diagnosis, the average

of stay for the patients with retinal detachment was about 4 days, while for patients with glaucoma (13 days) or ulcer corneal (12 days), the long-term hospitalization exceeded 12 days. The multivariate analysis showed that about 10% of the number of days spent in hospital (dependent variable) can be explained by the hospitalization diagnosis of and the type of intervention (R square = 0.102; p = 0.031) (tab. I).

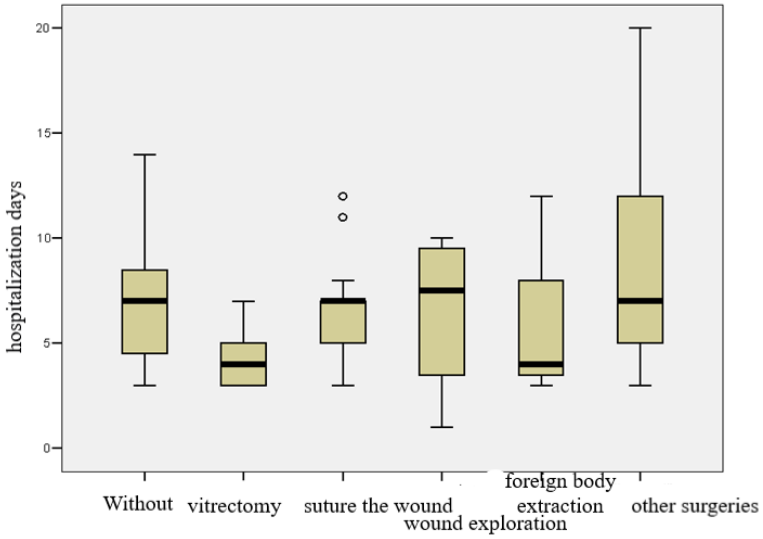

Fig. 6. Number of days spent in hospital related to the type of surgery

TABLE I

Multivariate analysis, variation in the number of days spent in hospital

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	,162[a]	,026	,010	3,422	,026	1,592	1	59	,212
2	,320[b]	,102	,071	3,315	,076	4,897	1	58	,031

a. Predictors: (Constant), DGinternare

b. Predictors: (Constant), DGinternare, Interventie

Correlated with the status of discharge, the number of days spent in hospital did not differ significantly (p = 0.909). The multivariate analysis confirmed that the number of days spent in hospital and the diagnosis after hospitalization are not good predictors in determining the condition at discharge (R square = 0.015; p = 0.425). Of the total study group, the discharge status of patients was 60.7% improved and 34.4% cured.

DISCUSSION

Due to the fact that "Sf. Spiridon" Hospital in Iaşi is the tertiary center in Moldova, Romania, being the only hospital in the region was the only hospital in the region that dealt with all the urgent ophthalmological pathology during COVID-19, the medical staff was exposed to suspected or confirmed COVID-19 patients. Several studies report what the attitude of the ophthalmolo-

gist would be and what the precautions to be taken during the risk of COVID-19 infection 19 would be. Ocular involvement has been reported in studies as being in 30% of cases, especially in those severe. The possibility of transmission in the ocular route is due to the presence of a similar enzyme converting angiotensin 2 (ACE2) receptors on ocular surfaces as well as on the host, the transmission being done through the exposed mucous membrane. Another route of transmission cited by studies is through the nasolacrimal duct, from where the virus migrates to the lower meatus. Ocular symptoms may occur 2 weeks after infection (3, 5). The main involvement being at the conjunctival level, the patient may present acute hemorrhagic conjunctivitis, with watery secretions, with pseudo-membranes that do not bleed by removal, being very important periocular and eyelid hygiene, topical treatments with antibiotics and anti-inflammatory drugs. Other manifestations such as superficial punctate keratitis have been reported as intraocular (3, 5, 6). Basak Bostanci Ceran and Serdar Ozates demonstrated the presence of ocular manifestations in the acute phases of the infection, thus including 93 confirmed COVID-19 patients in their study, who were having ocular symptoms besides systemic manifestations. As eye signs, 20% of them show hyperemia, increased secretion, epiphora, chemosis, follicular conjunctivitis and episcleritis and the most common symptoms were photophobia and itching. All had temperatures above 37 degrees, laboratory changes (neutrophilia, elevated CRP, elevated ESR, lymphopenia), all of which were associated in the study with ocular impairment (6). The authors of the study claim that all patients with conjunctivitis are considered COVID-19 suspects and should be consulted in a special room by an ophthalmologist wearing protective equipment (3).

Preventing the transmission of this infection through the eyes requires a series of recommendations and measures that ophthalmologists from all over the world have faced and followed and that we have also observed in our clinic. Regarding the clinical evaluations in outpatient services, avoiding the congestion of waiting rooms, reprogramming patients who were not urgently seen, disinfecting rooms with special disinfectant at each time interval, placing the UV lamp for 10-15 minutes were among the few useful measures in preventing the transmission of the infection. All patients in the emergency room presented for admission are recommended: epidemiological survey questionnaire, temperature monitoring, chest CT and COVID-19 emergency test (4, 6, 7, 8, 9).

Regarding the rules in the operating room, the studies provide a series of clarifications: banning the use of air conditioning (to reduce aerosol production), oxygen mask (reduction of nasopharyngeal flow), and decreasing operating time (operations performed by professional surgeons), while reducing the number of staff in the operating room. Wearing FFP 2 and 3 masks, FFP2 masks have a filtration rate of at least 94%, while FFP3 masks are the most filtering FFP mask, playing a key role and protecting against very fine particles such as asbestos, because many procedures produce aerosols. In ophthalmology: fragmentation of the nucleus by phacoemulsion and vitrectomy, where ultrasound-induced probe movement occurs at more than 50,000 Hz, with a significant production of aerosols. In addition to masks, ophthalmic operating rooms are usually ventilated with positive pressure systems, changing the air approximately 20 times per hour, with air passing through a high-efficiency particulate air (HEPA) air

filter, where the nanosized particles descend to be removed. Increasing the interval between surgeries to 45 minutes, thus allowing the disinfection and the action time of the used substances (4, 7, 10, 11).

Being the only hospital in the region of Moldova that was open during the pandemic, we faced many cases, mostly surgical. There were 619 patients in the emergency department in two months, of which an average of 10 patients were hospitalized per day, 61 patients (10%) required surgery being hospitalized with contusive trauma, wounds, retinal detachments, etc. The average duration of surgery was 45 minutes, and the average length of hospitalization was 6.3 days. Compared to the similar period in 2019, it was found that the number of general admissions decreased 5.6 times (342 *vs.* 61) and 77.6 times (233 *vs.* 3) for 1 day of hospitalization, due to restrictions on elective admissions (cataracts, strabismus, etc.), practically during the state of emergency, only the pathology that had to be surgically or medically resolved immediately was hospitalized.

Regarding the distribution of the most prevalent diseases that were treated during the emergency period, we have noticed that a large share of the admitted patients had a vitreoretinal emergency: retinal detachment (29.5%), postoperative infection (4.9%) or dislocated crystalline mass (1.6%). It is widely known that in rhegmatogenous retinal detachment, the prognosis is much improved if the surgery is performed in the first 3 days after the detachment of the macula (which is perceived by the patient as a dramatic decrease of visual acuity) (12). Such an acute event probably determined the patients to confront their apprehension about coming to a hospital during a lockdown period. Postoperative complications of cataract surgery are also susceptible to be rapidly diagnosed and emergency therapy is of utmost importance (13, 14,15, 16, 17,18). Special interdisciplinary procedures helped reduce the length of hospital stay (18). Another important percentage of patients had ocular trauma, either open globe (13.1%) or closed globe (24.6%), many of which normally would have been managed in county hospitals.

Conversely, elective surgeries like cataract extractions or macular procedures were practically stopped. While it is widely accepted that these conditions are slowly progressive or may be stable for months or years (16, 17), we are nevertheless wary about the possibility that many patients would present in the future with advanced stages or even complications (such as phacomorphic glaucoma or lens-related uveitis). Having no HEPA filter systems and having difficulties in creating circuits, the waiting time between surgeries increased and their number was drastically reduced. Since only half of beds were available, most cases were carefully selected and resolved in the previously established order. Exactly all the recommendations described above and mentioned in various studies in the literature were observed, as well as those suggested by the American Academy of Ophthalmology and the Romanian Ministry of Health if we compare the number of hospitalized patients.

CONCLUSIONS

Most of the ophthalmological activity during the pandemic was surgical, due to the large number of trauma cases from neighboring counties, being the only non-COVID-19 hospital in the northeastern region of Moldova (the other three public ophthalmology clinics being closed, as well as the entire private clinics-closed by law). Complying with the protocol suggested by the

American Academy of Ophthalmology for protection in ophthalmic surgery allows for standard eye care and safe surgery to maintain a sustainable application. Ultimately, the goal is to maintain patient confidence and secure access to both routine and emergency eye evaluation, while caring balances additional needs during an epidemic.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

FIRST YEAR OF THE COVID-19 PANDEMIC INFLUENCE ON BLADDER CANCER PATIENTS IN ONE SINGLE ACADEMIC UROLOGICAL CENTER FROM NORTH-EASTERN ROMANIA (Abstract): The COVID-19 pandemic created an unprecedented situation who made health systems to reorganize their resources and redeploy staff away from routine diagnostic, treatment and follow-up services. **Material and methods:** have studied retrospective the medical files of bladder cancer patients referred to our clinic between 1st of March 2019- 28 of February 2020 (group A) compared with those referred between 1st of March 2020-1st of March 2021 (group B). A total of 640 patients were included, 486 (75.94%) males and 154 (24.06%) females, aged between 22 and 92 years, with a mean age of 69.12 years (SD+/-9.62). Group A had 408 (63.75%) patients while group B 232 (36.25%). **Results:** We have noticed that anemia was significantly more often in group B (p=0.032), this has led to a higher necessity of preoperative blood transfusion (p=0.039) but with no differences regarding inflammatory syndrome or kidney failure incidence. Also, the hospitalization period (p=0.001) and the time from admission to surgery have been significantly shorter in group B (p=0.05). **Conclusions:** By trying to avoid hospitalization many patients are admitted with a poorer biological status. In addition, many bladder cancer cases will go undetected and untreated and once the pandemic has passed, we will face an excess in cancer-related mortality. **Keywords:** COVID-19, BLADDER CANCER, TURBT, HEMATURIA.

Since December 2019, when first cases of pneumonia of unknown etiology were reported to the World Health Organization (WHO), COVID-19 has spread worldwide causing WHO to declare it officially as a pandemic on 11th March 2020. The disease caused by coronavirus, a large family of single-stranded RNA viruses. They are responsible for severe acute respiratory syndrome coronavirus (SARS), the Middle Eastern respiratory syndrome coronavirus (MERS) (1). The rapid increase in the number of COVID-19 cases has led to fear and panic among health care professionals and the general population. This unprecedented situation has made health systems to reorganize their resources and redeploy staff away from routine diagnostic, treat-

ment and follow-up services.

COVID-19 could have a direct impact on urological/nephrological diseases. According to Hirsch *et al.*, 89.7% of mechanically ventilated patients due to SARS-CoV-2 developed acute kidney injury with 23.2% receiving kidney replacement therapy, in contrast to a 21.7% incidence of acute kidney injury and 0.2% requirement for kidney replacement therapy in non-ventilated patients (2). Also, this disease could have an indirect influence because in addition to wearing a mask, one of the most important recommendation to minimize the chance of viral transmission is social distancing however, this may not be possible for patients who require cancer-related treatments in hospitals.

In March 2020, a "state of emergency" was declared in Romania for a period of 30 days as of the 16th of March. The highest increase on COVID-19 case in first wave of the pandemic was in North-eastern Romania (47.1% of the infected medical staff nationwide, in April 2020). The neighboring Suceava County this area has often been referred to as the "Romanian Lombardy" , a suggestive comparison with the Italy's region which was severely affected by COVID-19 (3). We aimed to highlight the impact of the pandemic on bladder cancer patients on North-Eastern Romania in our region.

MATERIAL AND METHODS

We have studied retrospective the medical files of bladder cancer patients referred to our clinic between 1st of March 2019- 1st of March 2021. We have divided them into two groups: group A - patient admitted in our clinic between 1st of March 2019 and 28th of February 2020 (pre-pandemic) and group B - those treated 1st of March 2020- 1st of March 2021. We compared demographic data, laboratory findings and hospitalization period. Because between 1st of March 2020- 1st of March 2021 no cystectomy was performed in our clinic, we have not included this category of patients in the pre-pandemic group.

Statistical analysis was made using *t-Student* test for 2 Independent Means and *Chi-Square* test with Yates's correction, calculated online on http://www.socscistatistics.com/tests/ Default.aspx, statistical significance was defined as p value ≤ 0.05.

RESULTS

A total of 640 patient were included, 486 (75.94%) males and 154 (24.06%) females, aged between 22 and 92 years, with a mean age of 69.12 years (SD+/- 9.62). The demographic data on each group are shown in first table.

We have noticed that anemia was significantly more often in group B, this has led to a higher necessity of preoperative blood transfusion but with no differences regarding inflammatory syndrome or kidney failure incidence. Also, the hospitalization period and the time from admission to surgery have been significantly shorter in group B, as shown in second table.

TABLE I

The demographic data on each group

	Group A	Group B	p
No. Patients (n)	408 (63.75%)	232 (36.25%)

DISCUSSION

Bladder cancer (BC) is the 10th most common cancer worldwide, according to Cumberbatch *et al.*, it represents 3% of all malignancies, in 2018, 549,000 new cases and 199,000 deaths have been recorded (4). The unprecedented COVID-19 pandemic has placed a huge burden on healthcare systems worldwide with the requirement to treat large influxes of infected patients, many of whom require respiratory support. This led to a rapid reallocation of healthcare resources affecting urologic oncology practices. Moreover, professional associations (e.g.: European Association of Urology-EAU, American Urological Association-AUA) rapidly adapted the practice guidelines resulting in postponement of lots of medical and surgical procedures (5). According to these guidelines, in patients with small papillary recurrence/s or bladder tumors < 1 cm and history of Ta/1 low grade tumor, transurethral resection of the bladder tumor (TURBT) was to be defer up to 6 months, while those with bladder lesion and intermittent macroscopic hematuria or history of high-risk non-muscle invasive BC should be treated within < 6 weeks (5).

In the first pandemic year, almost half of patients we referred to our clinic compared to the previous year. This situation could have several explanations. First of them could be the reorganization of the county emergencies hospitals north-eastern Romania, many of the urological services could not treat patient for a period of time. In some countries, the situation was more dramatic. According to Maccagnano *et al.*, during March 2020 in the region of Lombardy an important number of urologists were reassigned to COVID-19 wards while four (out of 11) urological centers had no operative blocks dedicated to urology (6). The authors also noticed a significant reduction of the number of radical cystectomies and TURBT compared to March 2019. This led to an increased number of

patients evaluated for hematuria and hemostatic TURBT in academic centers northern Italy.

Bladder cancer patients in United Kingdom have been also affected by the COVID-19 impact on healthcare system. In a survey by Spencer-Bowdage *et al.*, between April and July 2020 in 37.5% of patients TURBT was postponed while in 18.8% of cases it was canceled (7). Regarding the cystoscopic surveillance, the authors noted that in 41.2% of cases the procedure was postponed while in 11.3% cancelled. In a survey by Teoh *et al.* on average, 28% of outpatient clinics, 30% of outpatient investigations and procedures, and 31% of urological surgeries had a delay of > 8 weeks (8). In another survey that included 2494 urologists from 76 countries, Gravas *et al.* revealed significant restrictions in outpatient examination and non-emergency surgery, the restriction was worldwide but lower in East/Southeast Asia, in addition elective operations that may require transfusion were performed only if patients were at high risk of disease progression, according to 47.3% of respondents (9).

Patient's fear is another important factor that is leading to delays in the diagnostic algorithm and a subsequent progression of undetected bladder cancers. Considering that according to Wong *et al*., BC occurs mainly in the elderly population with an average age at the time of diagnosis of 73 years, in our group mean age was of 69.12 years, many of them are worried about contracting COVID-19 and fear of its presence in healthcare facilities (10). To this is added the fact that, according to CDC COVID-19 Response Team, up to 80% of deaths due to COVID-19 occurred among adults aged ≥ 60 years (11). In Spencer-Bowdage's survey, a total of 76% of patients expressed some concern about attending hospital for their treatment and follow-up appointments (7). Macroscopic hematuria is a symptom encountered in 10% of patients with bladder cancer according to Sutton et al. and according to Gonzalez *et al*. only 1.2% of patients with microscopic hematuria have bladder cancer (12, 13). Therefore, such symptoms can be minimized and consequently overlooked by patients and doctors, in addition to the fact that, according to Wee *et al.*, most centers have reduced their outpatient capacity and are doing a triage to only select patients that are in most need of a cystoscopy (14). This could explain the higher incidence of anemia in our patients from group B. Although, in another Romanian urological center during spring 2020, hematuria was recorded only in 3.92% of hospitalized patients (15).

Although according to Wee *et al*., in order to accommodate the influx of COVID-19 positive patients, admissions to the urology, oncology or radiotherapy departments are being avoided, according to Méjean *et al.*, even in low-risk cases, urological procedures like TURBT cannot be postponed for more than 3 months (14, 16). More than this, according to Rexer *et al.*, other bladder cancer specific procedures like Bacillus Calmette–Guerin (BCG) instillations, cannot be reduced despite the COVID-19 crisis (17).

The hospitalization period was significantly shorter in group B because we wanted to avoid keep social distancing and avoid unnecessary contact with other patients and hospital staff. Also, the time from admission to surgery was shorter in group B mainly because more patients were referred as urological emergencies (e.g.: severe hematuria, anemia due to hematuria or urinary retention through blood clots)

because at least when "state of emergency" was declared in Romania, elective surgery have been forbidden and outpatient consultations were suspended (18).

CONCLUSIONS

The current COVID-19 pandemic has major impact in urological and especially bladder cancer patients worldwide. By trying to avoid hospitalization many patients are admitted with a poorer biological status. In addition, many bladder cancer cases will go undetected and untreated and once the pandemic has passed, we will face an excess in cancer-related mortality. It is the moral obligation of clinicians to sound the alarm in mass media about the risks to those who do not show up at the first signs of the disease.

NEWS

COMBINED LIFESTYLE FACTORS, ALL-CAUSE MORTALITY AND CARDIOVASCULAR DISEASE

The study performed a systematic review and meta-analysis to quantify the relationship of combined lifestyle factors (e.g., cigarette smoking, alcohol consumption, physical activity, diet and overweight/obesity) with the risk of all-cause mortality, cardiovascular mortality and incident cardiovascular disease (CVD). Methods PubMed and EMBASE were searched from inception to April 2019. Cohort studies investigating the association between the combination of at least three lifestyle factors and all-cause mortality, cardiovascular mortality or incidence of CVD were filtered by consensus among reviewers. Pairs of reviewers independently extracted data and evaluated study quality. Random-effects models were used to pool HRs. Heterogeneity and publication bias were tested. In total, 142 studies were included. Compared with the participants with the least-healthy lifestyles, those with the healthiest lifestyles had lower risks of all-cause mortality (HR=0.45, 95% CI 0.41 to 0.48, 74 studies with 2,584,766 participants), cardiovascular mortality (HR=0.42, 95% CI 0.37 to 0.46, 41 studies with 1,743,530 participants), incident CVD (HR=0.38, 95% CI 0.29 to 0.51, 22 studies with 754,894 participants) and multiple subtypes of CVDs (HRs ranging from 0.29 to 0.45). The associations were largely significant and consistent among individuals from different continents, racial groups and socioeconomic backgrounds. Authors concluded that given the great health benefits, comprehensively tackling multiple lifestyle risk factors should be the cornerstone for reducing the global disease burden. VACUUM ASSISTED STABILIZATION OF FLAIL CHEST-A COMPARATIVE CASE CONTROL PILOT STUDY (Abstract): Flail chest is associated with high rates of morbidity and mortality and management of such condition is a multidisciplinary task that should be based on pain control, judicious fluid administration, adequate pulmonary hygiene and management of the paradoxical movements of the thoracic wall. Many methods of treating rib fractures and flail chest have been developed over the years. Our aim was to evaluate a novel method of flail chest stabilization using negative vacuum pressure and compare it to a traditional method. **Material and methods:** 10 patients with flail chest from trauma admitted in Thoracic Surgery Clinic from Clinical County Emergency Hospital of Craiova and County Emergency Hospital of Targoviste were submitted to stabilization using Vacuum Assisted Closure kit. This series of patients were compared with 10 patients in whom a traditional method of stabilization was used, selected from the database of patients from the Thoracic Surgery Clinic of Clinical Emergency Hospital of Craiova, used as control group. **Results:** The 2 groups were comparable as no statistically significant differences were found regarding the gender, mean age, type of trauma, associated trauma, preexistent conditions, number of rib fractures, presence of pulmonary contusion, thoracic deformity. The parameters investigated: number of days with mechanical ventilation, number of days spent in ICU, total hospital stay, mortality didn't reach statistically significant differences. The only significant results found were for the pain scores recorded at 2 weeks and 1 month after discharge, the VAC stabilization being significantly better than traditional method. **Conclusions:** A larger study is required to establish if the advantages of the VAC assisted stabilization of the flail chest are superior to traditional treatment. **Keywords:** VACCUM ASSISTED, FLAIL CHEST.

Flail chest is associated with high rates of morbidity and mortality and management of such condition is a multidisciplinary task that should be based on pain control, judicious fluid administration, adequate pulmonary hygiene and management of the paradoxical movements of the thoracic wall. Also, when dealing with thoracic trauma it is adamant to conduct an accurate evaluation of the entire patient and classify the magnitude and severity of all the sustained injuries (1, 2).

Depending on the localization of the multiple broken ribs, flail chest can be (figs. 1 and 2) (I) anterior, mainly associated with sternum pathology, with fracture foci concerning only the bone component or the bilateral costochondral joints; (II) lateral or anterolateral, with fracture foci regarding both the bone and cartilage matrix of the ribs; (III) posterior or posterolateral (3).

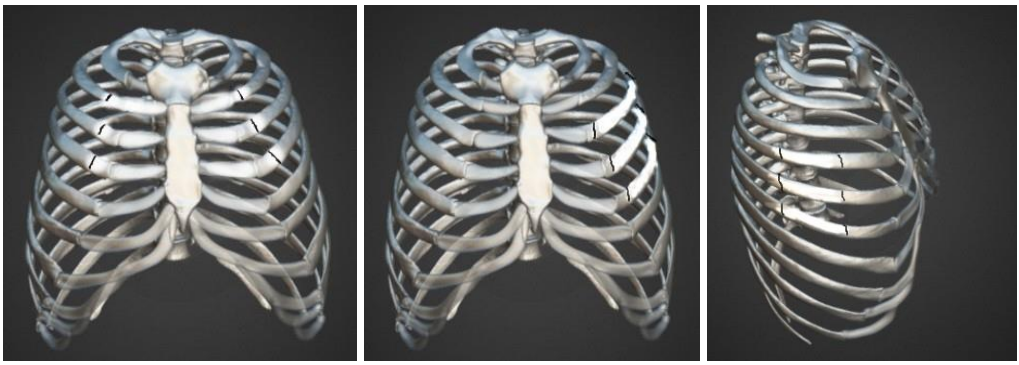

Fig. 1. Antero-lateral, lateral and anterior flail chest

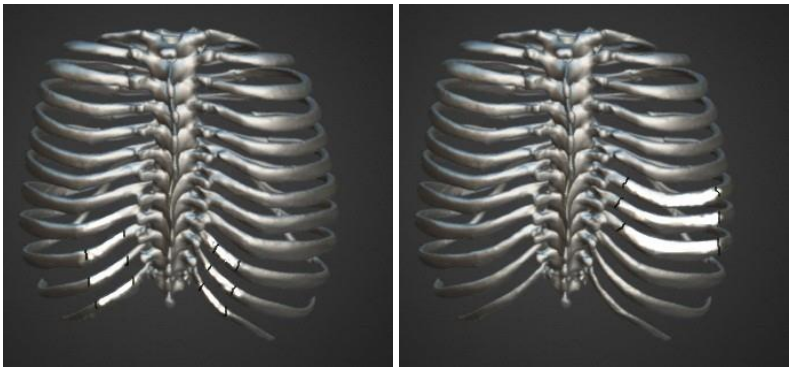

Fig. 2. Posterior flail chest and Postero-lateral flail chest

Flail chest is a common adverse effect of rib fractures, cardiopulmonary resuscitation, sternotomy and chest wall interventions (4). It prolongs hospitalization, pulmonary recovery and rehabilitation. To treat this type of pathology, many surgical techniques based on internal fixation have been described over the years.

From the methods Ambroise Pare described in the 16th century to modern bioresorbable plating systems, many methods of treating rib fractures and flail chest have been developed (3).

The Vacuum Assisted Closure®(14) device had proved significant improvement in the treatment of complications such as mediastinitis and thoracic wall instability in patients that have undergone thoracotomy (4).

VAC assisted therapy may also be used in the stabilization of the flail chest Topical negative pressure would have a stabilizing

effect on the thoracic wall. Expected advantages are stabilizing the paradoxical respiratory movements without surgical intervention, reducing associated complications of flail chest, spending shorter periods in the intensive care unit and reducing financial costs.

There are only 3 case reports that describe their experience using VAC therapy in managing flail chest: one describes thoracic trauma after a motor vehicle accident (5), one describes chest wall injuries sustained from cardiopulmonary resuscitation (6) and the later describes flail chest after surgical resection (7).

Our objective was to investigate if VAC therapy stabilization of flail chest brings better outcome compared to the traditional conservative medical treatment.

MATERIAL AND METHODS

We performed a comparative study of twenty cases, with severe trauma inducing flail chest with stern-costal fractures, in which ten cases received Vacuum Assisted Closure therapy in order to stabilize the paradoxical movements of the thoracic wall, whilst the other ten received standard conservative treatment.

Eligibility criteria

The study fulfilled the following eligibility criteria:

Target population: patients over 14 years who had suffered traumatic fractures of the ribs, with flail chest and paradoxical respiratory movements.

Comparator: Vacuum Assisted Closure therapy used to stabilize flail chest and conservative treatment.

Outcome: patient number of days spent on mechanical ventilation, number of days spent in the intensive care unit, number of days spent in the hospital, presence of pneumonia, rate of mortality and social reintegration.

10 patients with flail chest admitted the Emergency Clinical County Hospital in Craiova and the Emergency County Hospital in Targoviste were included in the series treated with vacuum assisted immobilization.

10 patients, as control, were selected from the database of the Thoracic surgery clinic from the Emergency Clinical County Hospital in Craiova treated by conservative measures.

The method used for VAC assisted immobilization consisted in an open-cell foam, covered the pieces with 3 metal bars, secured them with plastic bands and then covered the entire area with a transparent adhesive membrane, tightly secured to the skin and connected to the vacuum machine (fig. 3). As the device places suction, the system takes the shape of the body, and the space underneath the adhesive membrane becomes inflexible, stabilizing the chest wall and diminishing the paradoxical respiratory movements (5).

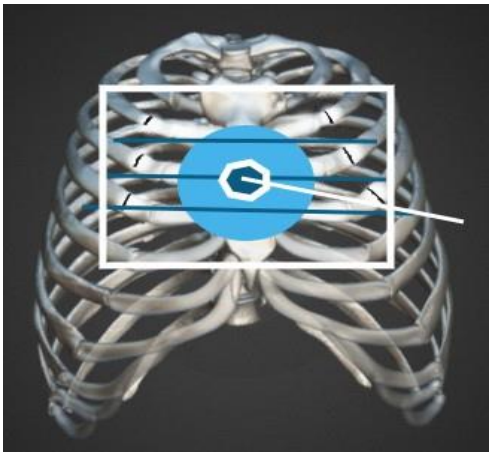

Fig. 3. VAC system on anterior flail chest

All of the patients included in the VAC series were treated with negative pressure for 14 days and were not discharged while wearing this system. The VAC suction pressure that we used was 200 mmHg.

Conservative treatment of flail chest consisted in immobilization of the flail segment by strapping the chest with adhesive tape or internal pneumatic stabilization for the more severe cases. Pain management, oxygen therapy and judicious use of fluid are also part of the medical treatment provided. The following data and parameters were recorded: patient age, sex, type of trauma that produced the lesions, number of fractured ribs, presence of pulmonary contusion, presence of thoracic deformity, number of days spent on mechanical ventilation, number of days spent in the intensive care unit, number of days spent in the hospital, presence of pneumonia, rate of mortality, associated trauma, preexistent patient pathology and social reintegration.

After discharge, patients were scheduled for two follow up visits, the first one was 2 weeks after the discharge and the second one after a month.

The patients were asked to estimate their current level of pain using a Wong Baker pain scale (8). The type of stabilization of the flail chest was decided in a multidisciplinary team consisting of specialists in thoracic surgery, intensive care and radiology.

We used the Mann-Whitney nonparametric test to compare the numerical variables recorded for the patients in our study. In order to compare categorical variables, we used the Chi square test. Level of significance was set for $p<0.05$.

RESULTS

The characteristics and data recorded for the patients submitted to VAC assisted stabilization of flail chest are presented in first table.

The data recorded for the patients who received a conservative and traditional method of flail chest stabilization are presented in table II.

The data regarding the patients, diagnosis, number of days spent in the hospital and in intensive care, mortality rate and treatment are presented in table III.

Hospitalization (mean +/- std dev)	19.30 ± 14.82	10.00 ± 7.07	0.080
Pneumonia (number of patients)	3	3	1.0000
Mortality	0.20 ± 0.42	0.10 ± 0.32	NS
Pain score 2 weeks (mean +/- std dev)	4.00 ± 1.58	6.13 ± 1.25	**0.014**
Pain score 4 weeks (mean +/- std dev)	1.89 ± 1.05	3.88 ± 1.36	**0.008**

There were no statistically significant differences between the 2 series of patients regarding the gender, mean age, type of trauma, associated trauma, preexistent conditions, number of rib fractures, presence of pulmonary contusion, thoracic deformity, number of days with mechanical ventilation, number of days spent in ICU, total hospital stay, mortality.

The only significant results found were for the pain scores recorded at 2 weeks and 1 month after discharge.

DISCUSSION

In our two groups the patients treated with VAC therapy spend less time on mechanical ventilation and in ICU, but more time in the hospital.

Prolonged hospitalization was determined by the multiple associated traumas that also required medical attention and to the fact that we did not discharge patients while receiving active VAC therapy. In the future we may obtain less hospitalization time if we discharge patients with the VAC system in place and instruct them to come for weekly medical visits.

Social reintegration is challenging after being treated for flail chest. Although both of our series presented with mild pain the after 1 month of being discharged (according to the Wong Baker pain score classification), for the VAC therapy group we obtained statistically significant results for the pain scores recorded at 2 weeks and 1 month after discharge.

In a country such as Romania where recovery programs and access to kinesitherapy workouts are scarce and strictly available in urban areas, using this stabilization method for flail chest may provide better social outcome.

Advantages of using VAC therapy in flail chest treatment include:

- The VAC machine is small, does not require a lot of space, can be easily stored and reused
- The patient can mobilize with the ma-

chine thus avoiding complications linked to excessive bed rest

- The system can be fast applied and can be used during transportation
- In order to install the VAC therapy system for flail chest, no special training is required
- Applying and taking off the system is easy and painless
- No anesthesia is required, avoiding the risks of general anesthesia and the unpleasantness of local anesthesia
- ICU stay is not required (unless other associated pathologies require ICU stay)
- If the patient requires immediate surgery, stabilizing the flail chest with negative pressure does not contradict other surgeries
- The foam dressings, the contact layer and VAC drape are the only single use components of the system. The VAC therapy unit, the Sensa TRACÔ Pad and the metal bars can be sterilized and reused, cutting further costs
- There is no need of different sizes for every patient
- Using the system does not require any type of incision, thus there is no risk of developing an infection linked to osteosynthesis and no aesthetic problems or complications linked to scars.
- The intercostals muscles are not affected because there is no need for a thoracotomy
- The VAC system is easily procured and is available in every country

Disadvantages of using VAC therapy in flail chest treatment include:

- Increased hospitalization
- While turned on the machine produces slight noise
- When applying the device, the patient might feel a slight pulling sensation and after some time they might experience pain or itching
- If one suffers a bilateral flail chest(for example anterior and lateral) 2 VAC systems are required of each side of the thorax
- The patient has to wear the system a considerable amount of time
- Showering while wearing the system may be difficult
- While the patient practices their daily exercises one must carry the therapy unit with them and be careful not to pull the Sensa TRACÔ Pad

After applying vacuum therapy for flail chest a few questions have come to mind. When is the best moment to apply this type of external fixation? As with other osteosynthesis methods, the sooner the fracture is treated, the better; applying the negative pressure device to the flail chest should be performed upon patient admission.

How much should we keep the device in place? The healing process of a fracture includes 3 phases: the inflammatory phase, the repairing phase and the bone remodeling phase. The first phase starts immediately after the lesion is produced and ends in approximately 1 week. In this phase the body immobilizes the fracture. The second phase starts within the first days after the fracture has occurred and lasts between 2-3 weeks. In this phase the human organism produces tissue and cartilage surrounding the fracture site, stabilizing it. The last phase is the bone remodeling phase and consists in removing woven bone and replacing it with lamellar bone and the resorption of excess callus. This process can last up to several months (9, 10, 11). The median healing time of a rib fracture is 2

months. We presume that it is safe to keep the negative pressure device on the flail chest up to 3 weeks in order for the repairing phase to end and that the flail segment no longer presents paradoxical respiratory movements.

If the patient is mechanically ventilated, should there be a relation between the internal continuous positive airway pressure and the external pressure executed by the vacuum device? The pressure that VAC therapy exercises on the chest should be small in order not to interfere with the pressure exercised by mechanical ventilation and avoid creating a situation similar to the physiopathology encountered in chronic obstructive pulmonary disease.

A lot of variables have to be taken into consideration and in order to assemble a clinical protocol regarding this matter; a mechanical thorax model should be the base of an experiment regarding how to balance the pressure in the vacuum therapy system and the mechanical ventilator. Applying a negative pressure device to a flail thoracic segment may provide better results to non-intubated patients. More studies are required in order to provide a more accurate answer on this subject.

Can the patient go home with the system in place and return for weekly check-ups? If the patient does not present any other life-threatening lesions and the respiratory constants are in normal range, we presume the patient can be discharged after one week and return for weekly controls.

In order to avoid skin lesions the pressure in the VAC machine should be adjusted in order to either provide small periods of low pressure or small periods without any pressure exercised on the chest.

Further study is necessary in order to elaborate a standard therapeutic algorithm of VAC external fixation in flail chest.

CONCLUSIONS

External fixation of flail chest using Vacuum Assisted Closure seems to improve respiratory outcome, stabilize the chest wall and reduce paradoxical respiratory movements.

The system is not hard to apply, can be quick and easily procured, and it can be used during transportation. In order to apply this method of fixation, no thoracotomy and no anesthesia are required. It is cost efficient and does not demand special training.

This method of stabilization may be used when other stabilization methods are either not available or not recommended due to the patient's serious condition.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

NEWS

HEPATIC NEUROENDOCRINE TUMOUR

Primary hepatic neuroendocrine tumor (carcinoid) is an extremely rare type of neuroendocrine tumour (between 60-90 cases are reported in the literature). Metastatic neuroendocrine tumor from the gastrointestinal tract to the liver is far more common. Some patients present with carcinoid syndrome. Elevated 5-HIAA and/or gastrin levels have been reported. Histologically, the tumor has features of classic neuroendocrine tumor (trabecular and pseudo glandular pattern) and dense core granules demonstrated by electron microscopy or by immunohistochemistry (positive staining by chromogranin antibody). There is speculation that the tumor might arise from ectopic pancreatic tissue in the liver or through differentiation from biliary epithelium. There are no specific imaging features, and cases are diagnosed retrospectively. One case report described an imaging appearance on ultrasound and contrast-enhanced CT similar to focal nodular hyperplasia. Somatostatin-receptor nuclear medicine studies (In-111 pentetreotide - Octreoscan) is positive. Given the rarity of the finding, an investigation for an extrahepatic primary carcinoid tumor is necessary. No standard treatment exists. Surgical resection has been performed. (Morgan M, Jones J. *Hepatic neuroendocrine tumour*. https://radiopaedia.org/articles/hepatic-neuroendocrine-tumor?lang=gb).

AORTIC ENDOTHELIAL CELL PROLIFERATION INDUCED BY EXOSOMES OBTAINED FROM iPSC UNDER THE ACTION OF VARIOUS MODULATORS (Abstract) **Background**: Extracellular vesicles (also known as EVs), secreted naturally by all cells, are known to act as mediators for intercellular communication. **Aim**: The goal of our study was represented by the quantification of rat aortic endothelial cell proliferation in culture in the presence of pluripotent stem cells (iPSC), chemically-induced from rat aortic smooth muscle cells (in co-culture) or in the presence of exosomes obtained, as a supernatant, from the culture medium of the latter cells, in the presence of 0.5 µM trichostatin A, 1 µM 6-mercaptopurine, 2 µM triamterene and 2 µM metformin. **Material and methods**: We used flow cytometry to quantify cell proliferation, using a membrane-permeable, tetramethylrodamine-based cellular tracking agent, 48 hours after inclusion in the culture medium. **Results**: The best proliferation for aortic endothelial cells, in the presence of exosomes obtained from the culture supernatant of pluripotent stem cells, chemically-induced from vascular smooth muscle cells, was obtained when grew these latest cell types on 3D biosupports and treated with 2 µM metformin. **Conclusions**: It is suggested that epigenetic changes, genome stabilization, and, especially, reprogramming of energy metabolism, result in the release of exosomes from induced pluripotent stem cells that have the ability to significantly amplify aortic endothelial cell proliferation in culture. **Keywords:** iPSC, GENOME STABILIZATION, ENERGY METABOLISM REPROGRAMMING, AORTIC ENDOTHELIAL CELL, AORTIC SMOOTH MUSCLE CELL.

Regenerative medicine has promised, since statutory, to meet two of the most stringent needs of modern organ transplantation, i.e., transplant that does not induce immunosuppression and, at the same time, ensuring an inexhaustible organ source. In absolute ideal way, organs obtained by bioengineering would be manufactured using patient own biomaterials, so both cells and support media, in which cells can be incorporated and allowed for a time to mature to regenerate, finally, the organ in question. While many research groups focus on the feasibility of this type of approach, very few truly target the immunogenicity of supports, which are lately developed for organs bioengineering (1).

Reprogramming of human cells, trans-

formed and functionally and morphologically differentiated into induced pluripotent stem cells (iPSC), already has a multitude of applications in basic biology, but also in drug development and, last but not least, in transplantation. The derivation of human iPS cells initially required a number of vectors to integrate into the genome, but it has been shown that these approaches might create mutations and then limit the usefulness of the obtained cells, in both research and clinical applications. More recently, these techniques have been able to be replaced by ones that have almost completely overcome these drawbacks (2).

The administration of vascular cells derived from pluripotent stem cells, fully immunologically compatible, obtained by vascular bioengineering, in the replacement therapy of autologous cells, associates a huge clinical potential. On the other hand, the industrial-scale production of vascular lines specific to each patient, for inclusion in regenerative cell therapies, is totally dependent on cell multiplication and differentiation under extraordinarily well-defined and reproducible conditions (3).

Multipotent mesenchymal stem cells are also potential candidates for innovative cell-based regenerative therapies. However, the mechanisms underlying the differentiation of this cell type and other important functions for tissue engineering remain far from known. Recently published data suggested a key role for intercellular contacts in mesenchymal stem cell differentiation processes (4).

The goal of our study was represented by the quantification of rat aortic endothelial cell proliferation in culture, in the presence of pluripotent stem cells, induced from rat aortic smooth muscle cells (in co-culture) or in the presence of exosomes obtained, as a supernatant, from the culture medium of the latter cells, in the presence of 0.5 μM trichostatin A, 1 μM 6-mercaptopurine, 2 μM triamterene and 2 μM metformin.

MATERIAL AND METHODS

The experiments began by multiplying young rat aortic smooth muscle cells (meaning a small number of passages in culture), grown in a complete DMEM environment, which stimulates proliferation, being improved in terms of composition with 2 mM L-glutamine, as well as with a series of classic antibiotics, represented by 100 U/ml penicillin and, in addition, 100 μg/ml streptomycin, and a concentration of 10% decomplemented FBS.

To obtain pluripotent stem cells induced from rat aortic smooth muscle line cells, we used a prior described and adapted chemical technique (5), completed with 5-bromo-2'-deoxyuridine, AM580 and "2i" inhibitors (6, 7).

In order to verify the importance of biologically active matrices in the development and functioning of induced pluripotent stem cells, the cells were multiplied, after stabilization, using as attachment factors, on the surface of flasks, collagen type IV, fibronectin, laminin and even a 3D biosupport, i.e., Alvetex type (Reinnervate gift). All of these were used in accordance with the manufacturer's instructions.

On the other hand, the rat aortic endothelial line cells were grown and multiplied in approximately the same way as vascular smooth muscle cells, except that we used DMEM/Ham F12 medium in a ratio of 1:1 and a factor for cell attachment to the surface of flasks (collagen type I).

For exosome separation, the culture medium of pluripotent stem cells induced from rat aortic smooth muscle cells was centrifuged up to 100,000 xg (8).

The active substances we used for the var-

ious experiments and protocols were: 0.5 µM trichostatin A, 1 µM 6-mercaptopurine, 2 µM triamterene and 2 µM metformin.

Methodologically, we used flow cytometry to quantify cell proliferation. Proliferation of pluripotent stem cells induced from aortic smooth muscle cells and endothelial cells was evidenced by a membrane-permeable, tetramethylrodamine-based cellular tracking agent, 48 hours after inclusion in the culture medium.

All the experimental data we obtained during the research were statistically extensively processed by the One-Way *ANOVA* test, completed only in conditions of absolute necessity with the Student-Newman-Keuls test.

RESULTS

Proliferation of pluripotent stem cells induced from aortic smooth muscle cells was evidenced by a cell-tracking agent, permeable from the outside to the inside, based on tetramethylrodamine, after 48 hours from inclusion in the culture medium, and flow cytometry. This cell tracking agent is very well retained intracellularly and detectable (due to the intensity of the fluorescence signal) for up to 72 hours. It has an extremely low cytotoxicity and does not affect cell viability or proliferation. The maximum excitation / emission is 541/565 nm (orange).

In a series of experiments, a number of aortic endothelial cells were treated with 0.01% exosomes obtained from the supernatant of pluripotent stem cells induced from aortic smooth muscle cells, which had previously been treated with 0.5 µM trichostatin A, an inhibitor relatively nonspecific of HDAC (histone deacetylase) type 1, 2, 3, 6, 7 and 9.

The best proliferation for aortic endothelial cells, in the presence of exosomes obtained from the culture supernatant of pluripotent stem cells derived from vascular smooth muscle cells and treated with 0.5 µM trichostatin A was obtained when grew these latest cell types on 3D biosupports (fig. 1).

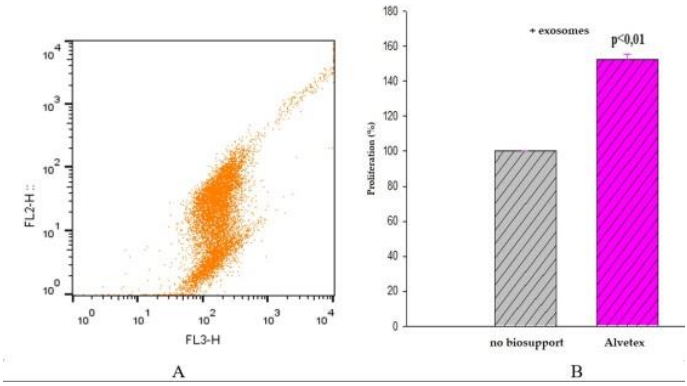

Fig. 1. Aortic endothelial cell proliferation in monoculture and in the presence of exosomes at a concentration of 0.01%, obtained from pluripotent stem cells induced from aortic smooth muscle cells, multiplied on 3D support and treated with 0.5 µM trichostatin A, evidenced by flow cytometry (representative image for this type of experiment) (A). The analysis of the flow cytometry results (n = 5) shows that the proliferation was 152.14 ± 2.79% as compared to that obtained without biosupport and considered to be in this case 100% (B). p <0.01 as compared to the lack of specific biosupport.

In other experiments, a number of aortic endothelial cells were treated with 0.01% exosomes obtained from the supernatant of pluripotent stem cells induced from aortic smooth muscle cells, which had previously been treated with 1 µM 6-mercaptopurine, a stimulant/major inducer of HDAC type 1 (fig. 2).

Furthermore, the derived pluripotent stem cells were treated with 2 µM triamterene, a pharmacologically active substance, considered a stabilizer of the genome, reducing its instability and mutations (fig. 3), and 2 µM metformin, considered a reprogrammer of energy metabolism (fig. 4).

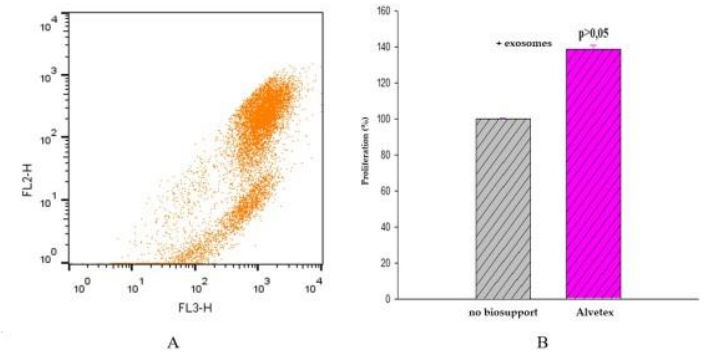

Fig. 2. Proliferation of aortic endothelial cells in monoculture and in the presence of exosomes at a concentration of 0.01%, obtained from pluripotent stem cells, multiplied on 3D support and treated with 1 µM 6-mercaptopurine (A). The analysis of the flow cytometry results (n = 5) shows that the proliferation was 138.29 ± 2.81% as compared to that obtained without biosupport (B). p <0.01 as compared to the lack of specific biosupport. p> 0.05 as compared to the absence of 6-mercaptopurine.

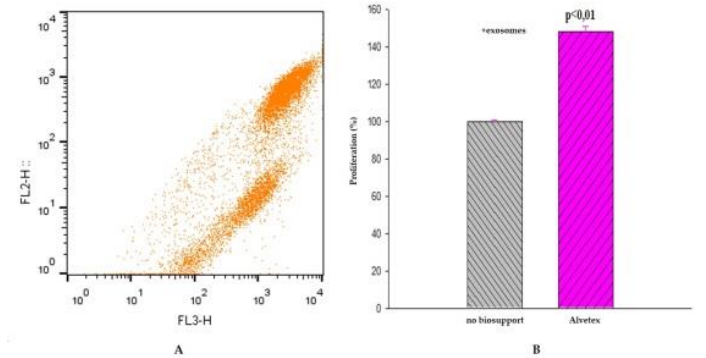

Fig. 3. Aortic endothelial cell proliferation in monoculture and in the presence of exosomes at a concentration of 0.01%, obtained from pluripotent stem cells, grown on 3D support and treated with 2 µM triamterem (A). The analysis of the flow cytometry results (n = 5) shows that the proliferation was 148.72 ± 2.99% as compared to that obtained without biosupport (B). p <0.01 as compared to the lack of specific biosupport. p> 0.05 as compared to the lack of triamterene.

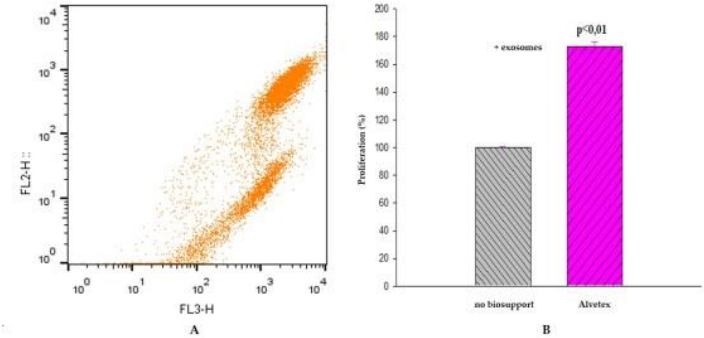

Fig. 4. Proliferation of aortic endothelial cells in monoculture and in the presence of exosomes at a concentration of 0.01%, obtained from pluripotent stem cells, grown on 3D support and treated with 2 μM metformin (A). The analysis of the flow cytometry results (n = 5) shows that the proliferation was 172.54 ± 4.22% as compared to that obtained without bio support (B). $p < 0.01$ as compared to the lack of specific biosupport. $p > 0.05$ as compared to metformin absence.

DISCUSSION

Given their ability to grow and differentiate, human-induced pluripotent stem cells represent a well-characterized cellular source that can almost unlimited, and can be used for the processes of mass generation of vascular cells in everything is patient-specific, even without any ethical concerns. Vascular line cells, derived from human pluripotent stem cells, are perfect for vascular disease modeling studies, given that these cells retain the disease-causing mutation unaltered, which could be crucial for the complete expression of the disease phenotype (3).

Acute limb ischemia is a condition in which tissue necrosis occurs as a result of arterial occlusion, which in many cases can lead to limb amputations. Both endothelial cells and vascular smooth muscle cells are absolutely necessary for the regeneration of peripheral arterial tissues in the post-ischemic stage. However, it is difficult to isolate and multiply the primary endothelial cells and, at the same time, the vascular smooth muscle cells, from the same patient, in order to initiate therapeutic angiogenesis. Induced pluripotent stem cells have been and are considered to be particularly useful stem cells, given the potential for multicellular differentiation. A series of studies have looked at the therapeutic efficacy of endothelial cells and smooth muscle cells, both derived from induced pluripotent stem cells, in the murine peripheral artery disease model. Simultaneous transplantation of these two derived cell types significantly improved blood flow and increased the rate of recovery of the affected limbs. This compares with single endothelial cell transplantation or vascular smooth muscle cells (9, 10).

Extracellular vesicles, secreted naturally by all cells, are known to act as mediators for intercellular communication. They can carry important loads to the recipient cells, such as nucleic acids, a series of proteins and lipids, which basically reflect the changes that occur in the cells of origin. Therefore, extracellular vesicles have been recognized as potential and important theranostic agents that could be used suc-

cessfully for diagnosis, treatment, and prognosis (11).

Extracellular vesicles are known to be important mediators of cell-cell communication. Thus, they are involved in many types of cellular, physiological and pathological processes, including immune regulation, but also cell proliferation and differentiation, in cell death, but also in angiogenesis. It is important to note that EVs can be used extensively as biomarkers of various pathophysiological conditions and/or as therapeutic agents, both as drug carriers or even as drugs themselves (12, 13).

Mesenchymal or stromal stem cells (also called MSCs) include progenitor cells of various origins (e.g., adipose tissue or umbilical cord - or Wharton jelly, respectively), which have a potential for multiple differentiation, and are currently the most studied stem cell population, even if we are talking about pre-clinical or clinical studies. Most of the effects of mesenchymal stem cells are due implicitly to their paracrine activity, which includes the massive release of extracellular vesicles. Extracellular vesicles are thought to have more health benefits in the process of tissue repair and regeneration as compared to their parental cells. There is a significant amount of research conducted both *in vitro* and *in vivo* on animal models, but also in clinical trials, in connection with a number of neurological diseases, cardiovascular diseases, but also liver, kidney and skin diseases. These studies can thus provide encouraging evidence for the pro-regenerative capacity of EVs derived from mesenchymal stem cells in various disease models, mediated by a multitude of mechanisms. Although the direct molecular mechanisms of action of these types of extracellular vesicles are still being investigated (14,15).

Within the modern and emerging concept of allogeneic benefit, regarding stem cell therapies, the use of extracellular vesicles obtained from allogeneic sources becomes the truly pragmatic choice, although a universal source of allogeneic cells still seems necessary. For example, the human placenta, basically a single temporary organ that can ensure the mutual coexistence of two allogeneic organisms, namely the mother and the fetus, could be a persuasive source of allogeneic stem cells, absolutely necessary for the development of therapeutic extracellular vesicles. The promotion of cell-free therapy offers outstanding prospective for the development of regenerative and/or reparative medicine (16).

Mesenchymal stem cells are being extensively researched for their potential application in tissue engineering and, at the same time, in regenerative medicine. Considering all the experimental data, it has recently been suggested that most of the beneficial effects of mesenchymal stem cells could undoubtedly be attributed to released extracellular vesicles and exosomes, respectively. Thus, the direct use/administration of mesenchymal stem cells does not appear to be necessary. Thus, *in vitro* and *in vivo* preclinical studies have suggested that exosomes derived from mesenchymal stem cells may exhibit a number of substantial therapeutic properties under many pathophysiological conditions, effectively restoring the functionality of a wide range of damaged or diseased tissues and organs. These beneficial effects of mesenchymal stem cell-derived exosomes can be demonstrated independently of the fluid or bodily anatomical origin of the mesenchymal stem cells and at the same time independent of cellular origin (e.g., bone marrow, or adipose tissue, or

umbilical cord, or urine, etc.). Furthermore, it is suggested that the effects of exosomes of this type could be greatly enhanced by changing the way donor mesenchymal stem cells are grown (e.g., multiplication under hypoxic conditions as compared to normoxic conditions, under 3D conditions as compared to culture in 2D formats), and/or by bio design (e.g., inclusion or association with specific loads) (17).

CONCLUSIONS

The best proliferation for aortic endothelial cells, in the presence of exosomes obtained from the culture supernatant of pluripotent stem cells induced from vascular smooth muscle cells, was obtained when we grew these last cell types on 3D biosupports.

The data obtained demonstrate first of all that the exosomes released into the environment by the induced pluripotent stem cells have a composition dependent on the intracellular pathways activated under various conditions.

Thus, it is suggested that generalized inhibition of histone deacetylases (HDAC), i.e. epigenetic changes, genome stabilization, and, especially reprogramming of energy metabolism, result in the release of exosomes from induced pluripotent stem cells that have the ability to significantly amplify aortic endothelial cell proliferation in culture.

UTILIZATION AND OUTCOMES OF EXTRACORPOREAL CO_2 REMOVAL ($ECCO_2R$): SYSTEMATIC REVIEW AND META-ANALYSIS OF ARTERIO-VENOUS AND VENO-VENOUS $ECCO_2R$ APPROACHES

Extracorporeal carbon dioxide removal ($ECCO_2R$) provides respiratory support to patients suffering from hypercapnic respiratory failure by utilizing an extracorporeal shunt and gas exchange membrane to remove CO_2 from either the venous (VV-$ECCO_2R$) or arterial (AV-$ECCO_2R$) system before return into the venous site. AV-$ECCO_2R$ relies on the patients native cardiac function to generate pressures needed to deliver blood through the extracorporeal circuit. VV-$ECCO_2R$ utilizes a mechanical pump and can be used to treat with inadequate native cardiac function. Existing evidence was sought by comparing the subgroups of patients supported on VV and AV-$ECCO_2R$ devices. Twenty-five studies including 826 patients were reviewed. 60% of patients (497/826) were supported on VV-$ECCO_2R$. The most frequent indication were acute respiratory distress syndrome (ARDS) and chronic obstructive pulmonary disease (COPD). ICU length of stay was significantly shorter in patients supported on VV-$ECCO_2R$ compared to AV-ECCO2R (15 vs 42 days, p=0,05). In-hospital mortality was not significantly different (27% vs 36%, p=0,26). Both VV and AV-$ECCO_2R$ provided clinically meaningful CO_2 removal with comparable mortality (Yu T, Tatum R, Saxena A, *et al.* Utilization and outcomes of extracorporeal CO 2 removal (ECCO 2 R): Systematic review and meta-analysis of arterio-venous and veno-venous ECCO 2 R approaches. *Artif Organs* 2021; 00: 1-12 / doi: 10.1111/aor.14130).

CLINICAL AND LABORATORY FEATURES OF ACUTE BACTERIAL MENINGITIS IN NORTH-EASTERN ROMANIA – PREDICTORS OF SEVERE PROGNOSIS

CLINICAL AND LABORATORY FEATURES OF ACUTE BACTERIAL MENINGITIS IN NORTH-EASTERN ROMANIA - PREDICTORS OF SEVERE PROGNOSIS (Abstract): Bacterial meningitis is a medical emergency; therefore, it is necessary to study the risk factors associated with poor outcome. **Material and methods:** We conducted a retrospective observational study at "Sf. Parascheva" Infectious Diseases Clinical Hospital from Iasi, between January 2015 and January 2018. The study included 145 patients diagnosed with bacterial meningitis who were divided into two groups: group I - surviving patients and group II deceased patients. Appropriate statistical methods were applied to the collected data. **Results:** Risk factors associated with an unfavorable development were age over 50, altered mental status, triad fever-headache-neck stiffness, as well as systemic damage, low Glasgow score upon admission or late presentation to the hospital. Factors associated with favorable prognosis in meningitis were the presence of headache, vertigo, and vomiting. **Conclusions:** The obtained results outline the recent clinical-evolutionary peculiarities of bacterial meningitis in the North-Eastern region of Romania in a group of demographically heterogeneous patients. **Keywords:** BACTERIAL MENINGITIS, RISK FACTORS, PREDICTORS.

Bacterial meningitis remains a neurological emergency and current epidemiological changes require a periodic adaptation of the method of early therapeutic approach even in developed countries. From this point of view, it is necessary to know as well as possible the profile of this disease as patients require immediate evaluation and treatment. The incidence of bacterial meningitis is almost 5 cases/100,000 adults in developed countries and may be 10 times higher in less developed countries. The most common etiological agents are *Streptococcus pneumoniae* (*S. pneumoniae)* and *Neisseria meningitidis (N. meningitidis)* which are responsible for almost 80% of all cases (1, 2).

Meningitis is an inflammatory condition involving the meninges and is classically manifested by fever, altered mental status, headache and neck stiffness. The disease is diagnosed by examining the cerebrospinal

fluid (3, 4).

The incidence, morbidity and mortality rate of bacterial meningitis varies and depends on several factors, such as age, geographical region, etiological agent, and immune status (4, 5). The epidemiology of bacterial meningitis has undergone changes with the introduction of vaccines (4). In underdeveloped countries, due to low vaccination coverage, the disease continues to strike, affecting high number of children (5). Therefore, the purpose of this research was to study the profile of the disease as well as to determine the risk factors associated with an unfavorable evolution in the North-Eastern region of Romania, characterized by substantial changes in the patient's behavior as well as the approach of this disease by different medical services.

MATERIAL AND METHODS

Study Design and Settings

We conducted a retrospective observational study at "St. Parascheva" Infectious Diseases Clinical Hospital, Iasi. The study included patients diagnosed with bacterial meningitis between January 2015 and January 2018 and was carried out with the approval of the Ethics Committee of "Gr. T. Popa" University of Medicine and Pharmacy from Iasi (No.8322/2.05.2018). The data was anonymized before it was used. To ensure the quality of the study we used STROBE (6).

Study Population

We analyzed the medical records of patients diagnosed with bacterial meningitis. The study group included 145 patients, aged over 18, divided into two study groups: group I – 105 patients diagnosed with bacterial meningitis, survivors and group II – 40 patients diagnosed with bacterial meningitis, deceased. Patients for whom, following lumbar puncture, the diagnosis of bacterial meningitis was not confirmed on the basis of laboratory criteria (7), as well as patients aged under 18 and patients with viral meningitis were excluded.

Definition and Data Collection

Bacterial meningitis diagnosis was based on the patient's history, the presence of clinical symptoms (such as headache, neck stiffness, altered mental status, fever) and analysis of laboratory parameters in the cerebrospinal fluid (CSF) and blood (7). The data collected also included information about the therapeutic approach of patients.

Outcome Measures. Results were reported according to the two groups considered. Demographic, clinical, imaging and laboratory parameters were evaluated in both groups and statistical significance was subsequently established.

Statistical Analysis

Data were systematized and centralized in an SPSS 18.0 database and processed using the appropriate statistical functions. A 95% confidence interval was used in data presentation. Indicators like minimum, maximum, mean, standard deviation, standard error were used for descriptive statistical analysis. Qualitative significance tests, such as the chi^2 test were used for comparing the distributions of frequencies and statistic power was establish depending on p-value (<0.005). Odds Ratio (OR) were used to measure the association between the exposure and the outcome. The *t-Student* test / *ANOVA* was used for comparing the means of any two normally distributed variables. The diagnostic accuracy was determined using receiver operating characteristic curves (ROC) and calculating the area under the ROC curve (AUC).

RESULTS

Demographic and clinical data

Among demographic characteristics, the factors which have correlated with the mortality risk were age over 50 (p=0.002, OR=3.07, 95%CI: 1.643-8.343) and behavioral factors such as smoking (p=0.001). Immunosuppression has also been associated with high mortality risk (p=0.001, OR=7.07, 95%CI: 2.435-20.534) (tab. I).

Alteration of mental status was observed in 36 of the patients who ultimately died and in 50 of the patients with favorable evolution (90% *vs.* 47.6%) and it was correlated with mortality risk (p=0.001, OR=9.90, 95%CI: 3.290-29.792). The classic triad: fever – headache – neck stiffness was present in a significant number of patients (p=0.001) - 27 cases in deceased group and 14 cases in survivors group (tab. I).

Analyzing the AUC, we concluded that only age ≥ 50 years old, immunosuppression, Glasgow Coma Sale (GCS) and altered mental status could be considered good predictors of mortality (tab. II).

Imaging and Laboratory findings

Cranial computed-tomography scan (Cranial CT scan) was performed in 35 deceased patients and 66 survivors (87.5% *vs.*62.9%). Cranial CT scan identified abnormalities of the central nervous system in 25 patients with unfavorable outcome and in 29 survivors (62.5% *vs.* 27.6%, p=0.001) (tab. III).

In deceased patients, the mean values of some hematological and biochemical laboratory parameters showed significantly higher differences between deceased and survivors patients: white blood cell count (WBC), neutrophils cells (PMN), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), urea, creatinine, glycemia, alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (AP) and bilirubin (tab. III).

The CSF examination in deceased patients revealed mean levels of white blood cells and albumin significantly higher than those recorded in survivors, while the mean level of lymphocytes was significantly lower (tab. III).

After analyzing the AUC (fig. 1), some hematological parameters like white blood cells (AUC=0.628), PMN (AUC=0.668), urea (AUC=0.791), ESR (AUC=0.658), CRP (AUC=0.939), creatinine (AUC=0.654), fibrinogen (AUC=0.534), PMN (AUC=0.750; C.I. 95%: 0.326-1.000), ALT (AUC=0.666), AST (AUC=659), glycemia (AUC=0.631), AP (AUC=0.623), bilirubin (AUC=0.644) counted as good predictors of mortality for bacterial meningitis.

From the CSF, only the albumin level (AUC=0.647) correlated with increased mortality rate and could be considered a good predictor of mortality (fig. 2).

The length of hospitalization was significantly higher in older patients (r= +0.163; p=0.05). In both deceased and surviving patients, the GCS at hospital

admission ranged from 3 to 15. The average score was significantly lower in the group of deceased patients (6.75 ± 4.47 *vs.* 13.63 ± 2.88; p=0.001). In the group of patients with poor outcome, hospital admission was generally late, the average level of days after the onset of the disease being significantly higher in this category (5.05 ± 1.05 *vs.* 3.75 ± 1.28; p=0.046) (fig. 3).

DISCUSSION

In our study, age over 50 years old and immunosuppression presented a 3- and 7-times higher mortality risk. Among comorbidities, diabetes mellitus was the most common (15%), as reported by literature (4-25%) (8). Other studies have also found older age to be a risk factor for poor outcome (9). Van de Beek reported immunosuppression as risk factor for meningitis with *S. pneumoniae*, *L. monocytogenes*, while immunosuppressed HIV-infected patients may present a risk of developing bacterial meningitis 8 times higher (2). Behavioral risk factors such as alcohol consumption and smoking were significantly correlated with the mortality risk in our study. By comparison, Larry *et al.* (4) described smoking as a risk factor for unfavorable evolution in adults and elderly. In the same study, they reported immunosuppression as a risk factor for meningitis (4).

Regarding the clinical symptoms presented by patients at admission, we found similar results as those in literature. The most common combination of symptoms found in our study was represented by fever, headache, neck stiffness and altered mental status (77.9%, 64.1%, 62.1% and 59.3%), in accordance with new data reports (2, 3, 9, 10).

In our study, 28.3% of patients presented the triad of fever - altered mental status - neck stiffness compared to data reports of 44% (9). In deceased patients, the association of fever with altered mental status and/or neck stiffness was significant, the risk of mortality being higher in those who presented this triad of symptoms in our study (OR=4.04).

Vomiting, vertigo and headache have been shown to be protective factors in bacterial meningitis. This is explained by the rapid hospital addressability of patients presenting these symptoms and therefore, an early diagnosis. So far, in literature no protective factors have been reported.

Among the meningeal signs represented by neck stiffness, Kernig 1-2 and Brudzinski 1-2, the most common was neck

stiffness, which was, also, suggested by the literature. The other signs were reported in 10-30% of patients. Their sensitivity and specificity are restricted in our study as well as in other studies (2).

The most common etiological agent in our study was *S. pneumoniae* (13.79%). These findings confirm previous data reports stating that pneumococcus is the most common cause of bacterial meningitis in adults, with rates between 35-50% (9, 12, 13). The low isolation rate of the etiological agent can also be explained by self-administration of antibiotherapy at home (21.01%). *S. pneumoniae* is also reported as the most common etiological agent (29.77%) isolated from the cases who died (14).

The analysis of laboratory results showed that cases with unfavorable evolution presented a higher inflammatory syndrome, thrombocytopenia, nitrogen retention syndrome, hepatocytolysis syndrome and elevated blood sugar. These parameters correlated significantly with the risk of death. As a result, systemic impairment may be an element of poor outcome, this aspect being also described in literature, as a risk factor for unfavorable evolution in patients with bacterial meningitis (9).

The CSF examination of patients with unfavorable outcome revealed that the mean levels of white blood cells and albumin were significantly higher compared to those recorded in survivors, which also confirmed the literature data (11).

Our study group reports a 27.6% mortality rate, different from the one revealed by Miftode *et al.* in a 10-year study conducted in the same North-Eastern area of Romania, which was 13.1% (15). The reported mortality rate by literature was 21-25% (9, 16). Other authors reported a relatively stationary mortality rate between 1998 and 2007 22.2%, and 24.5% between 2006 and 2015 (9, 16). The number of inpatient days was significantly higher in older patients, generating an additional risk of adverse outcome. Similarly with other reports, the average of GCS at the admission was significantly lower in the group of deceased patients (8). Patients with unfavorable outcome generally presented late for admission and the median time from onset of illness to hospital admission was significantly higher in the group of deceased patients.

CONCLUSIONS

Despite vaccination programmes lead to a decrease in the development rate of meningitis, this disease continues to be a challenge. In the present research, risk factors associated with unfavorable evolution were age over 50 years old, altered mental status, headache, fever - altered mental status - cervical stiffness triad, as well as systemic impairment, a low GCS upon admission or late presentation to the hospital. Factors that can be considered "protective" during meningitis were the presence of headache, vertigo and vomiting. In patients presenting these symptoms, the suspicion of meningitis was raised early on, and the diagnosis was confirmed without delay.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding the scientific research.

AEROBIC EXERCISE IMPROVES WORKING MEMORY IN AN ANIMAL MODEL OF PARKINSON'S DISEASE (Abstract): Regular physical activity is known to have extensive health benefits. Physical activity increases overall survival and reduces the risk of various chronic diseases such as cardiovascular disorders, cancer, hypertension, morbid obesity, depression, diabetes, and osteoporosis. Various molecular mechanisms may be responsible for the observed positive effect associated with physical activity. The most important one refers to the capability of physical exercise to influence the brain's chemistry and plasticity. **Material and methods:** we created 2 experimental groups of 6 rats each. First group received a physical exercise intervention, consisting of running on a treadmill adapted for small rodents, for a period of 2 weeks with training sessions composed of 3 sets of 5 minutes per day. The second group was used as control group. All the 12 rats received the pharmaceutical treatment with the substance was N-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) for the Parkinson disease model (20 mg / kg). **Results:** One-Way *ANOVA* showed that there was a statistically significant difference ($p<0.001$) between the rats which were randomly assigned to the control group and the rats assigned in the second group, which received the aerobic exercise intervention in regard to the spontaneous alternations' percent $F(1, 10) = 41.096$. These results show that aerobic exercise significantly increased spontaneous alternation percent by enhancing neurogenesis in our animal model of Parkinson's disease. Physical exercise improved memory acquisition, memory retention and reversal learning in the Y-maze task. **Conclusions:** aerobic exercise increases neurogenesis, which influences both learning and memory. The interactions between the aerobic physical exercise, neurogenesis, learning, and memory are very complex and remarkably dynamic. **Keywords:** AEROBIC EXERCISE, PARKINSON'S DISEASE, WORKING MEMORY, ANIMAL MODEL.

Regular physical activity is known to have extensive health benefits. Physical activity also increases overall survival and reduces the risk of chronic diseases such as cardiovascular disorders, cancer, hypertension, morbid obesity, depression, diabetes, and osteoporosis. Various molecular mechanisms may be responsible for the observed positive effect associated with physical activity (1). In addition, physical activity has also been discovered to have an influence on the brain's chemistry and plasticity

(2). The available data from the literature reports that the potentially critical mediators of the beneficial effects corelated with physical activity may be connected to the upregulation of neurotrophins and several nerve growths factors (3). Furthermore, other factors that contribute to the exercise induced neuroprotection may be related to the reduction of oxidative stress, enhancement of energy production, and mitochondrial function (4). Moreover, the central nervous system through the adaptive neuroplasticity may benefit from the physical activity (5). In animal models, the reported data shows that regular physical exercise triggers changes in rodents' central nervous system plasticity, these changes include synaptogenesis, increased glucose usage, angiogenesis, and neurogenesis (6). In human studies, scientists using MRI scans have demonstrated the positive effect of physical exercise in healthy individuals. For example, in a study on a healthy population, physical activity caused a statistically significant increase in the volume of gray and white matter (7).

Parkinson's disease is an age-related neurodegenerative disorder determined by an acute loss of the nigrostriatal dopaminergic neurons (3). Given that the number of people who suffer from Parkinson's disease is projected to significantly increase over the coming decades, interventions that might reduce morbidity and increase the quality of life are important. Currently the dopamine replacement therapy is considered to be the golden standard in treating symptoms of Parkinson's disease. Although this therapy has been proven to be effective for relieving the motor deficits, Parkinson's disease has a progressive course. Therefore, at this moment there is no entirely proven pharmacological therapy that can alter or slow down the disorder progression. Therefore, finding alternative, non-pharmaceutical therapies, which are easy to implement and have reduced costs, is vital in order to delay and slow down the dopamine neuron degeneration. Thus, physical activity can be an important complementary intervention to the pharmacological therapy to reduce the inherent decline corelated with the disease (8). Available evidence from the literature suggests that individuals who suffer from Parkinson's disease might benefit from physical activity in various ways. Physical activity may contribute to disorder-modifying effects in addition to general improvements in general health and quality of life of Parkinson's disease patients (9).

However, it is well documented that only a part of patients with the neurodegenerative disorder-Parkinson's disease, progress to developing major cognitive disturbances (10). Yet, minor cognitive deficits caused by this neurodegenerative disorder are common (11, 12). These minor cognitive disturbances can occur before motor symptoms develop, as demonstrated in siblings of patients with familial Parkinson's disease (13). The early minor cognitive deficits can be used to predict the development of dementia in the later stages of the disease (14, 15). It is these early minor cognitive deficits that do not respond well to dopamine therapies, and significantly alter the quality of life (16, 17). The before mentioned minor cognitive impairments include deficits in set-shifting (18), in switching tasks (19), in probabilistic reversal learning (20), in a delayed win-stay task connected to disfunctions in striatal and the prefrontal cortex (21), in long term memory (22, 23), and short-term memory (24, 25).

In human studies, results reported demonstrate that an active lifestyle and cardiovascular fitness are corelated with better cognitive function during aging (26, 27). Likewise, in animal models, increased physical activity in laboratory rodents has been reported to positively influence memory acquisition and retention in different behavioral tasks, which measure distinct forms of learning. For example, the results reported by some authors demonstrate that after one month of cardiovascular exercise, mice master the Morris water maze task faster when compared to the sedentary control mice (28, 29). In another study, rats that had a running wheel in their housing for 4-8 weeks presented a higher frequency in the freezing behavior in a fear conditioning task (30). In addition, in the same study, aerobic exercise also statistically significant increased memory retention in the passive shock avoidance task in mice (31). However, how exactly various aspects of the learning and memory processes are specifically influenced by exercise remains unclear.

Thus, in our experiment we examine the influence of physical activity, aerobic exercise on a treadmill, on learning and memory in more detail. The learning task that we used is the Y maze, a spatial reference memory task in which the rats have to memorize in which of two arms is the food reward. We differentiated between the possible effects of aerobic exercise on memory acquisition and on long-term memory retention. We also measured the consequences of cardiovascular physical exercise on reversal learning. Reversal learning is defined as the ability to use the acquired information to a new situation and to inhibit the previously used response (behavioral inhibition).

Therefore, in the present study, we analyzed the potential relationship between exercise, learning and memory, and Parkinson's disease. We hypothesized that the runner rats would master the Y-maze task better than the sedentary controls.

MATERIAL AND METHODS

Animals. Our experimental design was simple. We created 2 experimental groups of 6 rats each. First group received the physical exercise intervention, the second one was used as control group. All the 12 rats received the pharmaceutical treatment. We used adult male rats (8-10 weeks) Wistar breed with weight 30 g ± 2g. Animals were housed in cages in a controlled temperature room (22°C), a light / dark cycle of 12 : 12hrs. (starting at 08:00), with food and water *ad libitum*. Experiments took place within the *"Advanced Research and Development Center in Experimental Medicine"(CEMEX).*

Animals were brought into the laboratory at least 30 minutes before the start of the experiment for acclimatization (with temperature and background noise).

Pharmaceutical injection. The administration of the pharmaceutical was made with peritoneal injection. The substance was N-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) for the Parkinson disease model (20 mg / kg).

Aerobic exercise intervention. Intervention through physical exercise aerobic physical exercise was performed on a treadmill adapted for the small rodents, for a period of 2 weeks with training sessions consisted of 3 sets of 5 minutes per day.

Y Maze .Our model of the Y Maze was based on the previous validated model (32, 33). Alterations in working memory-related behaviors were measured in the Y-maze

test using a cardboard apparatus that consisted of 3 enclosed arms with measures of 30 × 5 × 15 cm, which converged on a triangular center area with measures of 5 × 5 × 5 cm. Spontaneous alteration was defined as the number of successive triple entry performances into each of the three arms without any repeated entries (32, 33). In addition, total number of entries into arms were also evaluated. The rate of spontaneous alteration performance, calculated as a percentage, was calculated as a parameter for the working memory-related behaviors. The total number of entries into arms was examined as a measurement of locomotor activity (32, 33). At the beginning of each experimental session, each rat was placed in the center of the maze, facing all three arms exactly before the session.

RESULTS

Our One-Way *ANOVA* showed that there was a statistically significant difference ($p<0.001$) between the rats which were randomly assigned to the control group and the rats assigned in the second group, which received the aerobic exercise intervention in regard to the spontaneous alternations percent $F(1, 10) = 41.096$.

The reported significantly differences among the two samples of rats were in the sense that the rats which performed the aerobic exercises presented a higher percent of spontaneous alternations ($x=69.29$, $s^2=4.09$) compared to the control rats ($x=52.18$, $s^2=5.06$) (fig. 1).

In addition, the maximum percent of spontaneous alternations was 76.47 in the aerobic exercise group and 58.33 in the control group. The minimum percent of spontaneous alternations in the aerobic exercise group was 64.71 and 46.15 in the control group of rats.

The second One-way *ANOVA* we performed indicated that the difference between the rats in the control group and the rats in the aerobic exercise group was also statistically significant ($p<0.001$) in regard to the number of total entries $F(1, 38)= 83.674$.

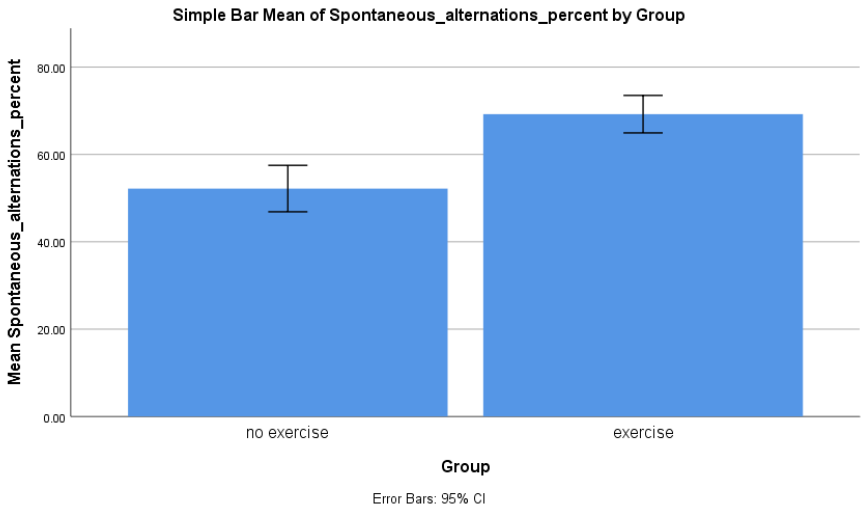

Fig. 1. Spontaneous alternations percent comparison between the two experimental groups.

The discovered significantly differences between the two groups of animals were in the sense that the rats which performed the aerobic exercise protocol had a higher number of entries (x=18.67, s^2= 2.58) compared to the control rats (x=14.17, s^2 = 1.16) (fig. 2).

Furthermore, the maximum number of entries was 22 in the aerobic exercise group and 15 in the control group. The minimum number of entries in the aerobic exercise group was 14 and 12 in our control group.

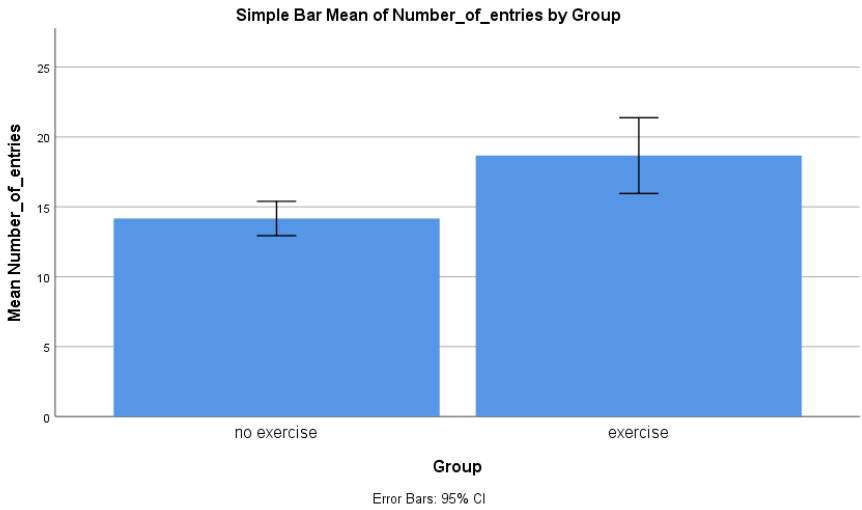

Fig. 2. Number of entries comparison between the two experimental groups.

DISCUSSION

In our animal model of the neurodegenerative-disorder Parkinson's disease, that we used in the present study, the experimental intervention consisting of sessions of aerobic exercise significantly increased both the spontaneous alternation percent and the total number of entries of Wistar rats. These uniform beneficial effects reported above are consistent with most of those reported in the literature. As noted in several previous studies, exercise has tended to increase the spontaneous alternation percent, the number of entries in these arms during the 5-minute test period (effects that reached statistical significance).

The deficits observed in our study in the rats which were sedentary, in the Y-maze, accompanied by those reported in other studies related object-place recognition and novel object recognition tests may be connected to an altered cholinergic system, as these tasks are impaired by administration of scopolamine, a muscarinic antagonist (34-36). The connection with our experimental design consists in the impairment observed in the cholinergic system in Parkinson' s disease. Patients suffering from this neurodegenerative disorder report cholinergic cell loss in the basal nucleus of Meynert (37). Furthermore, Lewy body pathology has been reported in this region as early as stage 3 of pre-manifest of Par-

kinson's disease (38). In addition, ChAT activity is also found to be reduced in the prefrontal cortex of patients who suffer from Parkinson's disease (39). Furthermore, individuals with Parkinson's disease present a decrease level of nicotinic ACh receptor binding in many cortical regions (40). Moreover, reported results from a study reported a significant accumulation of human a-synuclein in the cholinergic neurons located in the basal nucleus of Meynert (40). In the same study it was documented a 30% decrease in ACh levels in the cerebral cortex of mice from an animal model of Parkinson's disease. We can speculate that the same mechanisms revealed the presence of cognitive deficits in the present study. It is plausible to assume that the a-synuclein overexpression in the neurons, as the cholinergic neurons in the basal nucleus project to the cerebral cortex (41), has determined the decrease of cortical ACh, as it is documented to alter structures such as synthesis, packing into vesicles, and delivery of various of neurotransmitters (42).

The results from our experiment demonstrate that 14 days of aerobic exercise elevated the rate of acquisition in the Y maze, improved retention of already acquired memories, and positively influenced reversal learning. The fact that the aerobic exercise intervention had a positive effect on Y-maze's spontaneous alternations and number of entries is in concordance with other studies, using various learning animal models (28, 42, 43).

Therefore, we demonstrate in the present study that physical exercise not only increases the acquisition of a spatial learning function but also is helpful for the retrieval of spatial reference memory. Other author also reported results that demonstrated beneficial effects of aerobic exercise on memory retention (30, 31). Nevertheless, in these animal models, the rodents had access to a running wheel before the acquisition of the function. Some authors have speculated that, in these cases, the observed increased memory retention could be explained by the aerobic exercise-induced improvement of memory formation or an increase in memory retrieval. Therefore, in our experimental design, a difference between the effects of aerobic exercise on memory formation and memory retrieval could be made by providing the aerobic exercise intervention before the acquisition of the Y-maze task. In this way, we demonstrated that an improvement in physical activity can significantly increase memory retention by aiding memory retrieval.

Aerobic exercise intervention through running on a treadmill also facilitated reversal learning. During reversal learning, the rat has to adapt previously collected memory to a new situation. Because the majority of the features of the assignment were learned during training are still valid, the former memory trace does not need to be forgotten. As an alternative, the rodent modifies the current memory trace, which is necessary for the correct recovery of the memory and the adaptability to unlearn various details of the process, or to restrict the acquired response and to relearn new tasks.

Here we demonstrate that Wistar rats that had been exposed to a running treadmill for 14 days were significantly faster in learning and memorizing the new position

of the food in the Y maze than sedentary rats. These results suggest that physical exercise has a positive effect on the behavioral flexibility of a Wistar rat. Therefore, the performance in the Y maze regarding the memory acquisition assignment, memory retention or reversal learning was positively influenced by the aerobic exercise intervention.

There are various probable molecular mechanisms that can explain the observed exercise-induced improvements in learning and memory. The positive effects of treadmill running on Y-maze performance observed in our sample of rats, could also be due to elevated transcription or phosphorylation of genes that promote long-term memory acquisition (44-46). Therefore, an elevation in pCREB-positive cell number after 14 days of exercise could also probably occur in our experiment, exceeding the elevation in the number of DCX-positive cells, implying that aerobic exercise also caused CREB phosphorylation in other cells, not only in the recently built granule neurons.

In concordance, other available studies presented results according to which aerobic exercise has been shown to increase levels of different growth and neurotrophic factors (47-49). In addition, aerobic exercise has also been shown to promote cerebral blood circulation (50), angiogenesis (51) and cholinergic synaptic communication (43). All of these before mentioned positive effects on these various processes and markers may improve learning and memory. As the rats from the control group did not engage in any other activity, the positive effects of aerobic exercise could also partially be influenced by the enrichment of having a new daily activity and not by the physical exercise itself (52). It could therefore be mentioned, as a direction for future studies, the need to use a locked treadmill for the control rodents.

Further, some studies have reported reduced neurogenesis after various bouts of aerobic exercise in different animal models that measure different type of memories. A potential explanation for this reported decrease neurogenesis, is that it might assist in blocking interference between current memory traces and new ones. Therefore, 14 days after the rats have memorized the Y-maze model, the memory is probably stored in the cortex and retrieval is independent of the hippocampus (53, 54). Oxidative stress, inflammation and various vascular factors could be also implicated in this context (55-57). Nevertheless, being exposed again to the same model may revive the hippocampal memory trace and to reactivate it to an easier to alter state, may prove to be sensitive to disruption (58). Thus, it might be essential for the optimal retrieval of memories to partially decrease neurogenesis when memories are in this labile condition. Because new formed neurons may produce a vital substrate for the construction of new memory traces. Therefore, some author hypothesized that active suppression of neurogenesis during reexposure to a familiar context may help avoiding the formation of redundant memories and decrease possible meddling between the existing and the newly acquired memory trace.

CONCLUSIONS

To conclude, our results show that aer-

obic exercise significantly increased spontaneous alternation percent by enhancing neurogenesis in our animal model of Parkinson's disease. Physical exercise improved memory acquisition, memory retention and reversal learning in the Y-maze task. Taken together, these results imply that aerobic exercise increases neurogenesis, which influences both learning and memory. However, the interactions between the aerobic physical exercise, neurogenesis, learning, and memory are very complex and remarkably dynamic.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

NEWS

VITAMIN D AND OPHTHALMOPATHIAS A REVIEW

The importance of hydroxycholecalciferol as one of the liposoluble vitamins is known in the prevention and treatment of metabolic bone diseases (rickets, osteomalacia, osteoporosis) In recent years, however, information has increased on the importance of vitamin D3 in numerous organ systems and in the pathogenesis of various diseases, e g ophthalmopathies The immunological functions of vitamin D3 are the subject of studies dealing with autoimmune optic nerve disorders and their results appear to have a positive effect on demyelinating diseases It also plays an important role in maintaining the thickness of the retinal nerve fiber layer, but its additional administration has not been successful It appears that sufficient serum vitamin D3 levels may protect patients from deterioration in the form of a further attack of demyelination The course of diabetic retinopathy is probably also influenced by vitamin D3, by correlating the fact that its receptor and the enzymes of its metabolism are expressed on the retina Low serum levels of vitamin D3 may even trigger age-related macular degeneration Conversely, higher dietary intake of vitamin D3 may positively affect neovascularization The optimal level of hydroxycholecalciferol is between 60 and 200 nmol /l, the severe deficit represents a decrease below 25 nmol/l However, the demonstration of its protective character in connection with the mentioned diseases of the retina and optic nerve will require a sufficient number of studies to confirm the facts found so far about this rediscovered vitamin (Hribová, P, and Š Sotak "VITAMIN D AND OPHTHALMOPATHIAS A REVIEW " "VITAMÍN D A OFTALMOPATIE PREHĽAD" Ceska a slovenska oftalmologie : casopis Ceske oftalmologicke spolecnosti a Slovenske oftalmologicke spolecnosti vol. 2, Ahead of Print (2022): 1001-1004)

THE EFFECT OF AEROBIC EXERCISE ON MEMORY, DEPRESSION, AND ANXIETY LIKE SYMPTOMS IN AN ANIMAL MODEL OF AUTISM (Abstract): Given that individuals with autism frequently display various psychiatric symptoms, such as depression and anxiety, we decided to measure depression and anxiety like symptoms in an animal model of autism, and to test aerobic exercise as an experimental intervention for reducing these symptoms. **Material and methods**: Our experimental design consisted of 2 experimental groups of 6 rats each. The first group of rats received a physical exercise intervention, consisting of running on an adapted treadmill, for a period of 2 weeks with training sessions of 3 sets / 5 minutes per day. The second group was used as control group. All the 12 rats received the pharmaceutical treatment with the substance valproic acid (500 mg/kg). **Results:** Our One-Way ANOVA demonstrated that there was a statistically significant difference ($p<0.001$) between the rats which were randomly assigned to the control group and the rats assigned in the second group, which received the aerobic exercise intervention in regard to the spontaneous alternation percent in the Y maze, number of entries and time spent in the open arms in the Elevated Plus Maze, swimming and floating time in the Forced Swim Test and number of working and reference errors in the Radial Maze. Our results show that aerobic exercise significantly decreased anxiety and depression-like symptoms and also increased spontaneous alternation percent in the Y Maze in our animal model of autism spectrum disorder. **Conclusions:** Taken together, our findings imply that aerobic exercise might be considered a feasible intervention for patients with autism spectrum disorder in order to increase both learning and memory and to decrease anxiety and depression. **Keywords:** AEROBIC EXERCISE, AUTISM SPECTRUM DISORDER, ANXIETY, DEPRESSION, WORKING MEMORY, ANIMAL MODEL.

Despite the fact that the etiology of autism is still a matter of considerable controversy, it is well demonstrated that being exposed before birth to drugs such as thalidomide (1, 2) and valproic acid (3, 4) is partly responsible to the development of autism. Therefore, based on these evidence, animal models of autism have been constructed by prenatally exposing animals to valproic acid for a better measurement of the pathophysiological, morphological, and behavioral aspects of autism (5, 6).

The studies that examined thoroughly these animal models (7) have reported

results according to which prenatally exposed to valproic acid rats presented higher serotonin levels in the hippocampus and elevated levels of dopamine in the frontal cortex. Several clinical studies have observed a hyperactivation of the dopamine system in people with autism. For example, risperidone, which is known to block postsynaptic serotonin and dopamine receptors, have been reported in various studies to reduce tantrums, aggression, or self-injurious behavior in children with autism (8). In addition, in another study (9) the same risperidone has been demonstrated to significantly improve the repetitive, restricted, and stereotyped behavior in children with autism. All this evidence may suggest that people with autism could exhibit a hyperactivated dopamine system.

Furthermore, given that individuals with autism frequently display various psychiatric symptoms, such as depression and anxiety (10), we decided to measure depression and anxiety like symptoms in an animal model of autism, and to test aerobic exercise as an experimental intervention for reducing these symptoms.

We chose the forced swim test because it has been established to measure depressive behaviors in rats. When rats are positioned in a cylinder of water without any possibility for escape, they become immobile. This immobility behavior is believed to indicate an occurrence of depression-like behavior that prevents the rat from exhibiting active forms of coping with stressful stimuli (11).

On the other hand, the elevated plus maze measures anxiety like behaviors. This conflict test is based on a natural tendency of rats to actively explore a new environment, *versus* the aversive properties of an elevated open runway (12-14).

In addition, we also used Y-maze alternation which is a test of working memory also based on the natural tendency of rats to explore new territory whenever possible. The number of arm entries and the number of triads is recorded in order to calculate the percentage of spontaneous alternation. The spontaneous alternation percent is considered to measure short term spatial working memory (15).

Furthermore, rats also present various survival habits, such as instinctively locating and retrieving food (16). Spatial learning and memory are essential for recording information regarding spatial orientation and the environment. Therefore, we also used the radial arm maze for measuring spatial learning and memory in rodents. This commonly used maze allows for the measurement of spatial working and reference memory. A radial maze usually has a center area with eight arms radiating outward. At the end of each arm are located food sites. These food sites are not visible from the central area. Four arms have food at the distal end, and the other four arms do not have any. Throughout the trial part of the radial maze experiment, the rat must acquire food from all four arms of the maze. For each of the following trial, the same arrangement is used so that rats can memorize to gather food from all four arms without accessing the arms that do not have food in them. In this manner, two types of memories are examined during the maze task, working and reference. Examination of working memory implies rats re-enter in the same trial in previously entered arms. While the measurement of reference memory involves rats entering in each trial in the arms with no food.

Although the beneficial effect of physical exercise on children with autism spec-

trum disorder has been demonstrated in the literature and is presently recommended for reducing various symptoms by the National Center for Physical Activity and Disability, children with autism spectrum disorder rarely engage in physical activities (17-20). One explanation may be that these decreased levels of physical activities and exercises may be a result of the limited opportunities available for children with autism spectrum disorder (17). The social and behavioral deficits that are commonly present in children with autism spectrum disorder that make participation in activities with peers difficult, may explain these restricted opportunities (21). Therefore, social constraints, more than existing impairments, could be the limiting factor determining the low levels of physical activities observed in children with autism spectrum disorder (22).

In regard to the positive effect of physical exercise and physical activities, it has been studied the possible positive effect of physical exercise on stereotypic behaviors in children with autism spectrum disorder. In a small study on 3 children with autism spectrum disorder, with ages between 7 and 11, Kern *et al* investigated the effect of exercise on various symptoms of autism spectrum disorder (23). The results reported by the authors demonstrated that stereotypic behaviors diminished following vigorous jogging. Interestingly, no reduction in the frequency of the stereotypic behaviors was observed following mild intensity exercise (23). Therefore, a certain intensity might be necessary in order to promote optimal beneficial effects. In addition, in a similar article, Watters and Watters reported similar results in a sample 5 boys with autism spectrum disorder with ages between 9 and 11 years old (24). They discovered that the maximum decrease in the frequency of stereotypic behavior was observed following physical activity (jogging for 8-10 minutes) in comparison with academic work or television watching. Likewise, a study investigating a sample of three children with an age of 11 years old, with autism spectrum disorder, found that 15 minutes of continuous jogging significantly decreased stereotypic behaviors (25). The authors of this study also investigated the carryover of the observed decrease in stereotypic behaviors and reported that the behavior carryover was restricted to 90 minutes after the running (25). Therefore, the frequency of the physical activity might also be important when implementing such an intervention in order to observe positive effects.

Another group of authors conducted a systematic review evaluating the effects of physical exercise on the frequency of stereotypic behaviors of children with autistic spectrum disorder (17). This systematic review analyzed 7 studies which included a total of 25 children. From this total sample, twenty-two were children with ages between 6-15 years old and 3 were younger children with ages from 3 to 5 years old. In the studies that contained younger children in the sample, the physical activity intervention involved walking compared to jogging, only jogging, and jogging compared to ball playing (23, 26, 27). The results reported demonstrated that only jogging led to an observed decrease in stereotypic behaviors (27).

From the same systematic review, three studies had an experimental design that measured the possible positive effect that physical exercise might have on academic performance (28). Two studies out of three reported results that showed improved

academic performance following jogging (27, 29), while Watters and Watters found no significant effect of physical exercise on academic performance (24). In addition, another study found an additional positive effect of exercise, documenting a significant increase in on-task behavior (28).

Another interesting study that measured the effect of exercise on academic performance of children with autistic spectrum disorder found that jogging, at an intensity that elevated the individuals' breathing rate and caused flushed faces, lowered stereotypic behavior, and increased both on-task time and academic performance (27). In a similar study, but on a sample of 6 adults with autistic spectrum disorder, identical results were found (29). These results demonstrated that aerobic activity elevated the frequency of appropriate behavior and reduced off-task time in this sample of adults with autistic spectrum disorder.

In addition, in another study which used roller skating for 10 minutes as the aerobic exercise intervention, similar results were found in an 8-year-old child with autistic spectrum disorder. Their results showed a reduced level of stereotypic behavior and an increase level of on-task performance (30).

Therefore, the available data shows that aerobic exercise improves correct responding, increase on-task time, and decrease the frequency of stereotypic behaviors in older children (with ages from 6 to 15 years old) with autistic spectrum disorder (17). Regarding young children (3 to 5 years old), although few studies have explored such an effect their results are similar (30).

The purpose of this study was to determine whether participation in aerobic exercise improves memory and reduces anxiety and depression like behavior in an animal model of autism.

MATERIAL AND METHODS

Samples of adult male rats (8-10 weeks) Wistar weighing 30 g ± 2 g were formed. The animals were housed in cages in a temperature-controlled room (22 ° C) and a light / dark cycle. 12: 12h (starting at 08:00), with food and water ad libitum. The experiments were carried out within the "Advanced Center for Research and Development in Experimental Medicine – CEMEX". The animals were brought to the laboratory at least 30 minutes before the start of the experiment, to acclimatize it (with temperature and background noise).

Pharmaceutical injection - The administration was made with an intraperitoneal injection. The substance was valproic acid for the animal model of autism (500 mg/kg).

Intervention through aerobic exercise - Aerobic exercise was performed on an adapted treadmill for 2 weeks with training sessions consisting of 3 sets of 5 minutes each day.

Forced swim test. The forced swimming test consisted of rats individually being placed in a glass cylinder (45 cm high, 25 cm in diameter) containing 30 cm of water, maintained at room temperature during the test (25 ± 1.0°C). Subsequently, the rats were removed and returned to their cages after 15 minutes in water. They were placed in the cylinder again 24 hours later. The total duration of immobility in rats was measured during a 5-minute test. Rats were considered immobile when they remained floating passively in the water.

Y Maze. At the beginning of each experimental session, each rat was placed in the center of the maze, facing all three arms exactly before the session. Spontaneous altera-

tions in working memory-related behaviors were measured in the Y-maze test using an apparatus that consisted of 3 enclosed arms with measures of 30×5×15 cm, which converged on a triangular center area with measures of 5×5×5 cm. Spontaneous alteration was defined as the number of successive triple entry performances into each of the three arms without any repeated entries.

The Elevated Plus Maze. The elevated plus-maze, a standard paradigm to assess anxiety-related behavior in rodents, consisted of an apparatus with four arms, 49 cm long and 10 cm wide, elevated 50 cm above the ground, with two arms enclosed by walls of 30 cm high and the other two exposed. After accommodation to the test room for half an hour, each rat was placed at the junction of the four arms, facing an open arm and allowed to freely explore the maze for 5 min. The entries and time duration in each arm were recorded as indicators for anxiety.

Radial Maze. Our radial maze was an apparatus consisting of a circular center compartment from which 8 equally spaced arms draw out. Each arm was a stretched column of equal distance, the far end of which contained (or not) a food reward not visible from the center compartment.

RESULTS

Y maze

Our One-Way ANOVA showed that there was a statistically significant difference (p=0.001) between the rats in the control group and the rats which received the aerobic exercise intervention in regard to the spontaneous alternations' percent F (1, 10) = 22.011.

The reported significantly differences among the two samples of rats were in the sense that the rats which performed the aerobic exercises presented a higher percent of spontaneous alternations (x=88.72, SD=10) compared to the control rats (x=56.05, SD =13.7) (fig. 1).

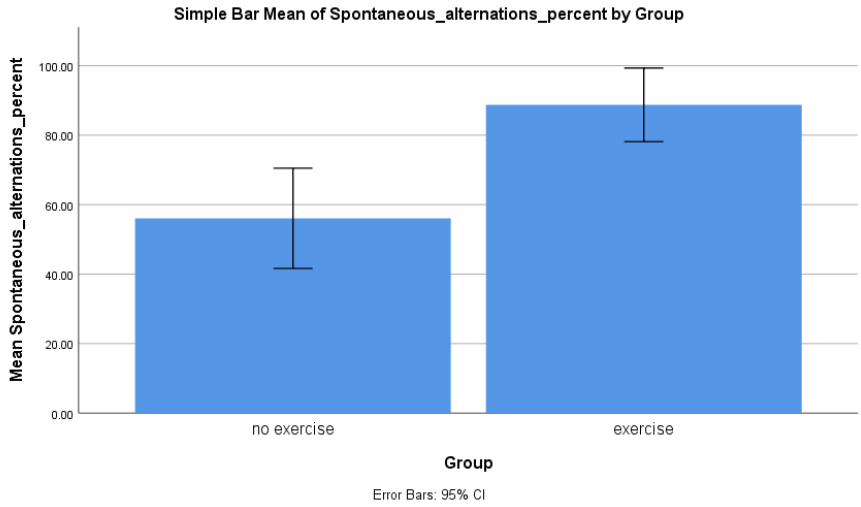

Fig. 1. Comparison of spontaneous alternations in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.011)

In addition, there was a statistically significant difference (p=0.004) between the rats in the control group and the rats assigned in the second group, which received the aerobic exercise intervention in regard to the number of entries F (1, 10) = 13.857.

The reported significantly differences among the two samples of rats were in the sense that the rats in the aerobic exercise group presented a higher number of entries (x=21.5, SD=4) compared to the control rats (x=10.83, SD =5.7) (fig. 2).

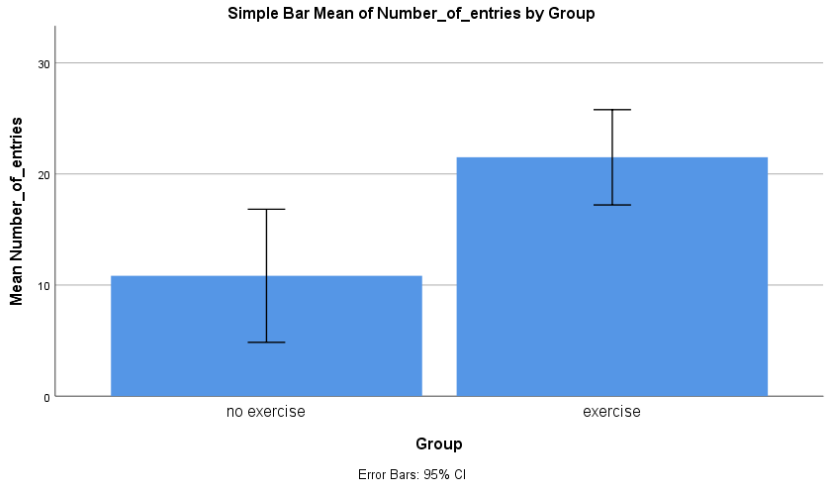

Fig. 2. Comparison of number of entries in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.004)

Elevated plus maze

In the elevated plus maze, there was a statistically significant difference (p=0.033) between the rats assigned to the control group and the rats which received the aerobic exercise intervention in regard to the number of entries in the open arms F (1, 10) = 6.154.

The reported significantly differences among the two samples of rats were in the sense that the rats which performed the aerobic exercises displayed a higher number of entries in the open arms (x=1.67, SD=0.5) compared to the control rats (x=0.33, SD =1.2) (fig. 3).

In addition, there was also a statistically significant difference (p=0.028) between the rats from the control group and the rats from the aerobic exercise intervention group regarding the time spent in open arms F (1, 10) = 6.644.

These significant differences were in the sense that the rats which performed the aerobic exercises spent more time in the open arms of the maze (x=8.33, SD=5.9) compared to the control rats (x=1.5, SD =2.5) (fig. 4).

However, there was a non-statistically significant difference (p=0.157) between the rats which were randomly assigned to the control group and the rats assigned in the second group, which received the aerobic exercise intervention regarding the number of entries in the closed arms F (1, 10) = 2.341.

Although the rats which performed the aerobic exercises presented a lower number

of entries in the closed arms (x=4.67, SD=1.8) compared to the control rats (x=6.83, SD =2.9) this difference was not statistically significant (fig. 5).

However, a statistically significant difference (p=0.028) was found regarding the time spent in closed arms (F (1, 10) = 6.644) between the rats in the control group and the rats assigned in the second group, which received the aerobic exercise intervention.

The reported significantly differences among the two samples of rats were in the sense that the rats which performed the aerobic exercises spent less time in closed arms (x=291.67, SD=5.9) compared to the control rats (x=298.5, SD =2.5) (fig. 6).

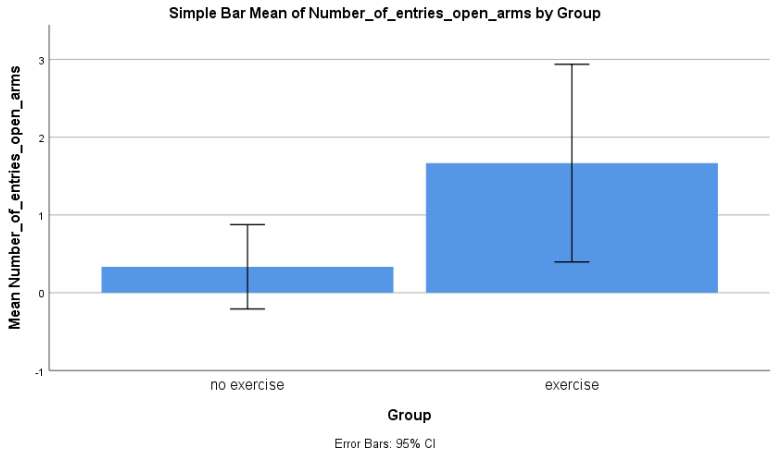

Fig. 3. Comparison of number of entries in open arms in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.033)

Forced swim model

In the forced swim model, we found a statistically significant difference (p<0.001) between the rats assigned to the control group and the rats assigned in the second group, which received the aerobic exercise intervention in regard to the swim time F (1, 10) = 9.653.

The reported significantly differences among the two samples of rats were in the sense that the rats which performed the aerobic exercises spent more time swimming (x=275.33, SD=19.7) compared to the control rats (x=226.67, SD=32.8) (fig. 7).

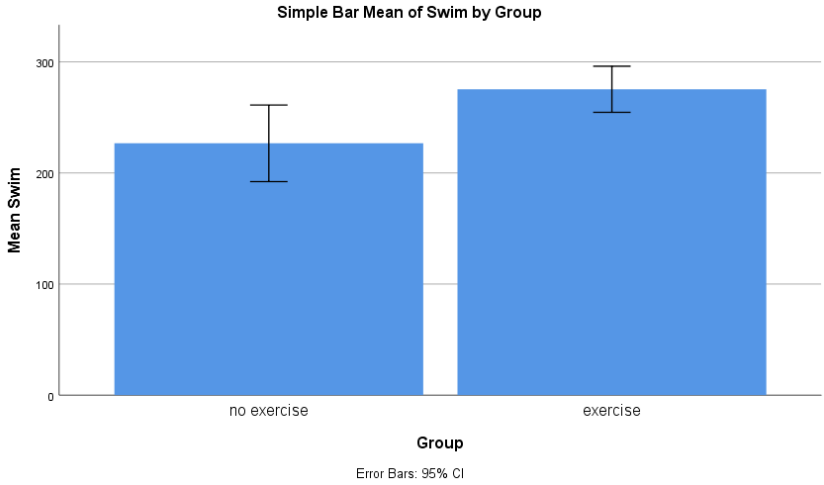

Fig. 7. Comparison of time spent swimming in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.011)

There was also a statistically significant difference (p=0.023) between the rats which were randomly assigned to the control group and the rats which received the aerobic exercise intervention regarding the floating time F (1, 10) = 7.215.

The reported significantly differences among the two samples of rats were in the sense that the rats which performed the aerobic exercises spent less time floating (x=21.67, SD=17.9) compared to the control rats (x=48.33, SD=16.4) (fig. 8).

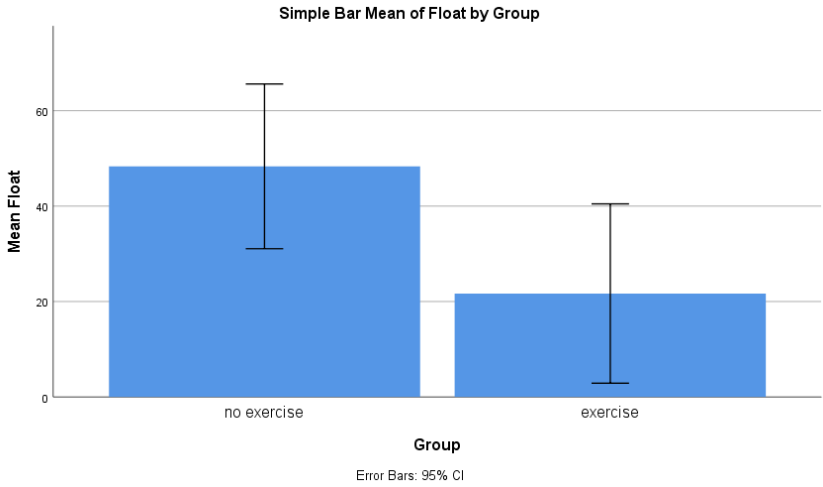

Fig. 8. Comparison of time spent floating in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.023)

In addition, there was also a statistically significant difference (p=0.023) between the control rats and the rats assigned in the second group, which received the aerobic exercise intervention regarding the mobility time F (1, 10) = 41.096.

The reported significantly differences among the two samples of rats were in the sense that the rats which performed the aerobic exercises presented a higher mobility time (x=278.33, SD=17.9) compared to the control rats (x=251.67, SD =16.4) (fig. 9).

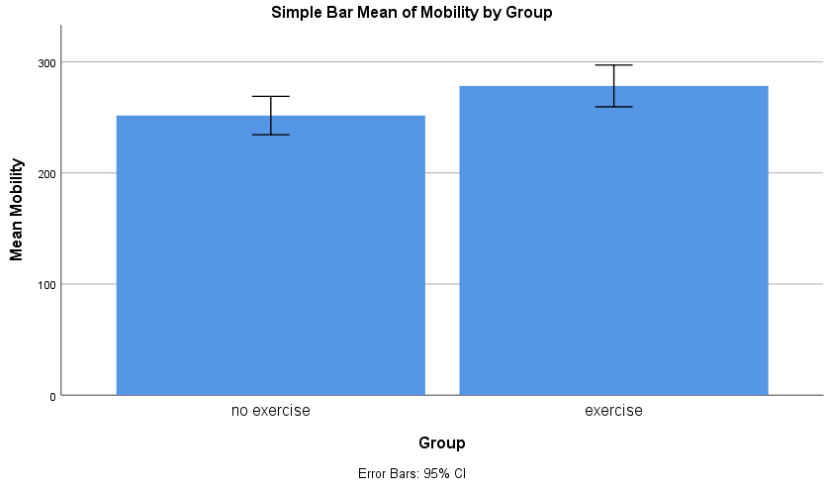

Fig. 9. Comparison of mobility time in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.023)

Radial maze

The results regarding the radial maze showed that there was a non- significant difference (p=0.139) between the rats which were distributed in the control group and the rats distributed in the second group, which received the aerobic exercise intervention in regard to the total number of entries F (1, 10) = 2.581.

Although the rats which performed the aerobic exercises presented a lower number of total entries (x=6.67, SD=1.2) compared to the control rats (x=9.33, SD=3.8) this difference was statistically non-significant (fig. 10).

However, also in the Radial Maze, there was a statistically significant difference (p=0.041) between the rats in the control group and the rats in the aerobic exercise intervention group regarding the number of working errors F (1, 10) = 5.517.

This significant difference among the two samples of rats was in the sense that the rats which performed the aerobic exercises made fewer working memory errors (x=0.83, SD=0.9) compared to the control rats (x=2.17, SD =0.9) (fig. 11).

In addition, the next One-Way ANOVA demonstrated that there was a statistically significant difference (p=0.04) between the rats which were distributed in the control group and the rats distributed

in the second group, which received the aerobic exercise intervention in regard to the number reference errors F (1, 10) = 5.538.

The reported significantly differences among the two samples of rats were in the sense that the rats which performed the aerobic exercises made fever reference errors (x=1.17, SD=0.4) compared to the control rats (x=3.17, SD =2) (fig. 12).

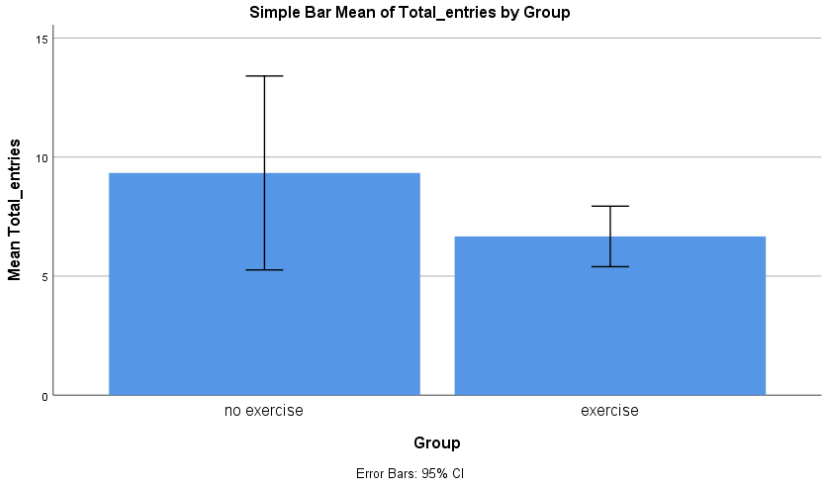

Fig. 10. Comparison of mobility time in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.139)

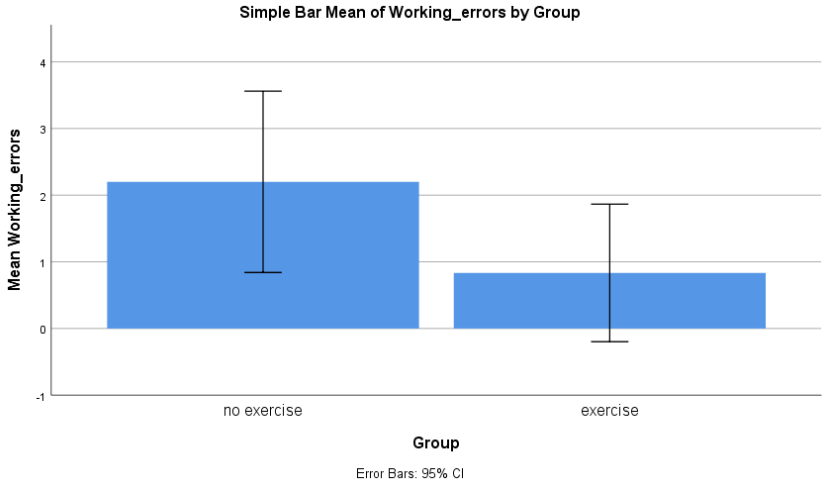

Fig. 11. Comparison of number of working memory errors in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.041)

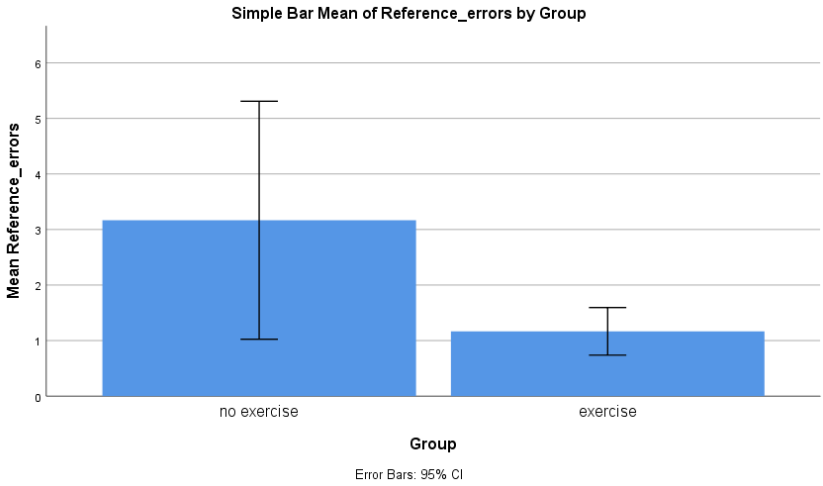

Fig. 12. Comparison of number of reference errors in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.04)

Nevertheless, there was a statistically non-significant difference (p=0.241) between the rats in the control group and the rats distributed in the aerobic exercise intervention group regarding the total time to complete the session F (1, 10) = 1.552.

Although the rats which performed the aerobic exercises presented a lower total time to complete the session (x=183.17, SD=90.6) compared to the control rats (x=213.42, SD =77), this difference was not statistically significant (fig. 13).

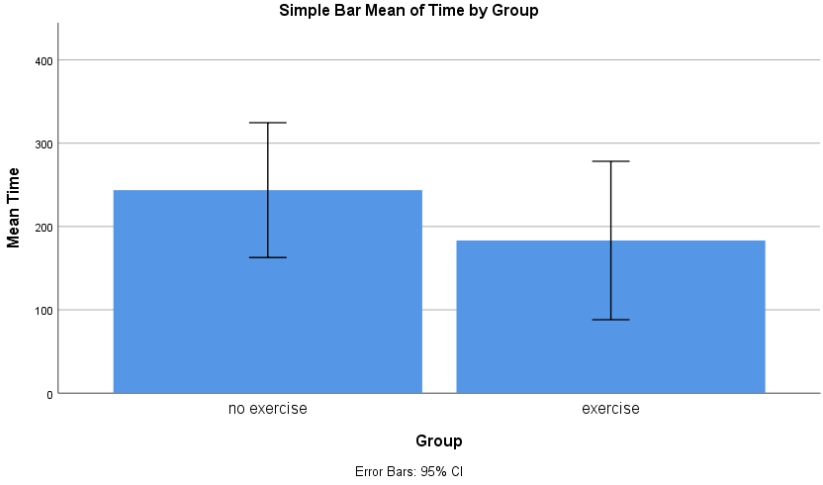

Fig. 13. Comparison of total time to complete the session in the control group *versus* the group receiving the exercise intervention in the animal model of autism induced by valproic acid injection (p=0.241)

DISCUSSION

In our animal model of autism spectrum disorder induced by valproic acid, experimental intervention with aerobic exercise significantly reduced the symptoms of this condition in Wistar rats. These uniform beneficial effects reported above are consistent with most of those reported in the literature. In the forced swim test, as is evident in several previous studies (31, 32), exercise tended to increase the total time of swimming, struggling and mobility and to decrease the time of immobility during the 5-minute test period (effects that have reached statistical significance). One possible explanation would be that although physical activity, as an antidepressant treatment, increases hippocampal BDNF (brain-derived neurotrophic factor) and provides protection against the harmful effects of stress on the hippocampus, the exercise in the current study produced behavioral effects in the test of forced swimming. are comparable to those associated with pharmaceutical antidepressants. Therefore, it appears to be a correlation between hippocampal BDNF levels and motor activity in the forced swimming model after aerobic exercise.

However, some of the previous studies on exercise and the forced swimming test also had mixed results. Some groups of researchers have reported an increase in swimming time during forced swimming after performing aerobic exercise (33-35), and some have not found any significant change or even reported a decrease in the swimming time (36, 37). Therefore, unlike this study, exercise decreased swimming time in other studies, and physical activity also decreased the observed duration of struggle and mobility. It is possible that these contradictory results are explained by the experimental conditions specific to each design, such as the strain of the animals, but especially the duration, type, or the intensity of exercise (38). For example, a longer duration of exercise (two weeks or more) may be required to produce behavioral activation in the forced swim test. Therefore, the significant results of our experiment could be explained by the duration of the intervention through aerobic exercise. In our experimental design, the aerobic exercise was performed on an adapted treadmill for 2 weeks with training sessions consisting of 3 sets of 5 minutes each day.

It is also important to note that the forced swim test in our experiment was performed with a water depth of 30 cm, which is significantly higher than the water depth used by some other studies, 20 cm (32, 38). The depth of the swimming pool could be important because the ability of the animals to feel the bottom of the cylinder with their tails can significantly affect their behavior in the forced swimming test (39).

In addition, the time of day can also be a very important factor contributing to the final results, as our animals were tested at the beginning of the day and it was observed that rats participate in a significantly lower escape-oriented activity towards the end of the day, a result that may be associated with low anxiety and differential hormone levels (40). In addition, it is very important to note that exercise has been reported to produce significant anti-anxiety effects (41-43), and the significant increase in swimming time, fighting and mobility observed in our study may reflect high anxiety during the forced swimming test. Therefore, it has been questioned in recent years whether the decrease in swimming time during the forced swimming test reflects behavioral despair or may denote something completely different (44-46), such as a more relaxed mental state, or a better physical condition that may led to an easier maintaining of the floating posture.

For example, some research groups have explained the decrease in swimming time observed in forced swim test as an indicator of a reduced stress response (40). Decreased anxiety after exercise may also explain the lack of correlation between hippocampal BDNF levels and motor activity in the forced swim test. Increased motor activity, although a specific response to antidepressant stimuli (exercise in our case), may not correlate with hippocampal neuro-protection.

Also, in this study, aerobic exercise intervention had significant effects on our model of autism spectrum disorder obtained by injecting valproic acid. Valproic acid combined with exercise decreased immobility behaviors and also produced a tendency to increase swimming time. Other investigators have shown that selective noradrenaline reuptake inhibitors increase the duration of swimming during the forced swim test and significantly less of this specific behavior is observed in animals treated with serotonin selective agents (47, 48). Because exercise is known to enhance the central release of both norepinephrine and serotonin (49-51), physical activity may have contracted the selective behavioral effects of valproic acid used to induce patterns of autism spectrum disorder. In addition, the serotonin component released by exercise may be responsible for a calming effect on animal behavior.

Our results indicate that exercise interventions may decrease depression-like behaviors in the forced swimming test to a level comparable to regular antidepressants. In addition, previous research has shown that not all antidepressants increase swimming time as well as exercise in our experiment. SSRIs (serotonin reuptake inhibitors), in particular, have been reported to produce a significant positive response in the tail suspension test, but often fail to do so in the forced swimming test (39). However, serotonin reuptake inhibitors are now among the most effective and prescribed antidepressants (39). Yet, some research groups have made changes to the forced swim test that still allow the measurement of antidepressant-like behaviors induced by serotonin reuptake inhibitors, such as increasing the duration of swimming (47, 52).

Regarding the observed anxiolytic effect of physical exercise on our autism animal model, it has been proposed as an explanation an implication of dopamine in fearful emotional responses in the rats (53-55). The mesocortical dopamine system which is projecting from the midbrain to the frontal cortex, is demonstrated to be sensitive to physical and psychological stressors (56). Therefore, physical exercise might reduce the anxiety like symptoms in rats by reducing stress markers in our rats' autism model.

Regarding another possible positive effect that physical exercise might have, studies that measured serotonin levels in the frontal cortex, could not find any significant changes in frontal cortex serotonin levels during and after the physical exercise intervention. Therefore, the observed positive effects of physical exercise in the present study might be explained by the changes in frontal cortex dopamine levels during and especially after the physical exercise intervention.

As previously demonstrated in other studies (57) we found significant differences between the control rats and the rats which received the aerobic exercise intervention in a measure of baseline anxiety as revealed by a 5-min trial on the elevated plus maze. Therefore, in the elevated plus maze control rats showed a significant higher frequency in anxiety-like behaviors compared to rats from the aerobic exercise

intervention. Specifically, the rats which performed the aerobic exercise before being tested in the elevated plus maze presented a higher number of open arms entries and spent significantly more time in the open arms. These findings are important for our autism model given that previous studies have revealed differential effects in stressor reactive and stressor resilient mouse strains to various psychogenic, neurogenic, and systemic stressors (58). This increased anxiety in BTBR mice (BTBR mouse is an inbred mouse strain with face validity as a preclinical model of the core autism symptom domains) was demonstrated in the literature by a decreased amount of time spent in the open arms of the apparatus and an increase in the time spent in closed arms of the apparatus (59). The inverse relationship between the amount of time spent in the open arms and the level of anxiety is of course well demonstrated (60), while several other studies have also shown that an increase in the time spent in the closed arms in the elevated plus maze is a sign of anxiety (57, 61). Therefore, the elevated time spent in open arms observed in the rats which received the aerobic exercise intervention might demonstrate the importance of physical exercise intervention in reducing several autism spectrum disorder symptoms.

The large number of closed arms entries is also considered a sign of high anxiety in rats (62). Interestingly, we were unable to find significant differences between our two experimental groups regarding the number of entries in the closed arms in the elevated plus maze, although the rats from the aerobic exercise group spent significantly less time in the closed arms. Although the entry in the closed arms of the maze is not a typical measure of abnormal social behavior, it has been suggested that it may prevent their engagement in reciprocal social interactions (57, 63, 64). Perhaps it was the energy expenditure from the aerobic effort which prevented us from observing significant differences in the time spent in the closed arms of the elevated plus maze.

Therefore**,** in our animal model of autism spectrum disorder, the rats that received the exercise intervention spent significantly more time swimming compared to the control rats. Moreover, control rats had a longer duration of immobility (measured in seconds) compared to the rats in the exercise group. Therefore, the intervention through aerobic exercise has statistically significantly decreased the level of symptoms similar to depression in the model of forced swimming.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

THE PROLONGATION OF THE ANTINOCICEPTIVE EFFECTS OF NOVEL NANOSYSTEMS ENTRAPPING DICLOFENAC SODIUM IN SOMATIC PAIN IN RATS (Abstract): The prolongation of the antinociceptive effects of novel nanosystems entrapping diclofenac sodium in somatic pain in rats (Abstract): The **aim** of this study was the investigation effects of nanosystems incorporating diclofenac sodium on the nociceptive reactivity in rats. **Material and methods**: In the experimental study were used 24 white healthy, non-genetically modified Wister rats, weighing 200-250 g, with a uniform distribution by sex, purchased from the National Medical-Military Institute "Cantacuzino" for Research and Development, Băneasa, Bucharest. The substances were given orally as follows: Group I (control): distilled water 0.3 mL/100 g body weight, Group 2 (DCF): 5 mg/kg body weight (kbw) diclofenac sodium; Group 3 (DCF-ves): lipid vesicles entrapping diclofenac sodium 5 mg/kbw. The experimental protocol was approved by the University Committee for Research and Ethical Issues, in compliance with the international ethical guidelines regarding the handling of laboratory animals. Data were statistically processed using *SPSS software for Windows 17.0* version and ANOVA one-way method. **Results**: Lipid vesicles containing diclofenac, stabilized with chitosan were designed. The measurements indicated a mean size of 562 nm and a mean Zeta potential of +45 mV, thus suggest a reasonable stability of the colloidal suspension. The use of DCF resulted in a prolongation of the latency period response to thermal noxious tail stimulation, with a statistical significance during 90 minutes in the experiment. The treatment with DCF-ves was accompanied by a substantial increase of the latency time reaction in the interval between 2 hours and 8 hours after the administration. **Conclusions:** Both entrapped and non-entrapped DCF proved to have an important analgesic effect in tail flick test in rats. The administration of lipid vesicles as carriers for DCF demonstrated a prolonged antinociceptive activity, compared to the non-entrapped drug in this cutaneous pain model in rats. **Keywords:** LIPID VESICLES, DICLOFENAC SODIUM, TAIL FLICK, NOCICEPTION, RATS.

Obtaining and studying various nanoformulations incorporating pharmacologically active substances, represents a modern direction of research and is an attractive starting point for the identification of new drug delivery systems with therapeutic

benefits in various pathological conditions. The study is in line with modern trends in scientific research, which aims to assess the effects of drugs or drug delivery systems in various pathological conditions (accompanied by pain and inflammation), which can be found in medical practice. Experimental investigations will be able to highlight the advantages of using original nanoformulations containing diclofenac on the cutaneous nociceptive reactivity in rats.

Among all nanosystems developed, liposomes have proven to be some of the most established drug delivery systems due to their small size, good biocompatibility, increased biodegradability, hydrophobic and hydrophilic character, low toxicity and immunogenicity (1, 2). A vast literature describes the feasibility of encapsulating a wide range of drugs, including anticancer drugs, antimicrobial agents, analgesics, peptide hormones, enzymes and genetic materials, in the aqueous or lipid phases of liposomes that have shown an enhanced therapeutic activity and/or reduced toxicity compared to the non-liposomal formulations, in various preclinical models or in clinical trials (3, 4).

One of the most interesting and, at the same time, with great clinical utility is the use of nanosystems that incorporate non-steroidal anti-inflammatory drugs (NSAIDs), with the idea of prolonging the pharmacological effects and at the same time, of reducing the adverse effects, especially the gastrointestinal irritation (5).

Diclofenac is a phenylacetic acid derivative, structurally related and with pharmaco-logical properties similar to mefenamic acid and sodium meclofenamate. It blocks the both cyclooxygenase-1 (COX-1) and cyclooxygenase-2 (COX-2), being used to counteract the acute and chronic pain associated with inflammatory pathology. There are evidence that diclofenac inhibits lipoxygenases, as well as phospholipase A2, and activates the antinociceptive nitric oxide-guanzine monophosphate (GMP) pathway. These additional actions may explain the high potency of diclofenac, which is considered one of the most powerful NSAIDs (6).

Diclofenac is an active drug belonging to class II (according to the biopharmaceutical classification system) with a high degree of permeability, but with a low solubility (7). Characteristically, it has an acidity constant of level 4, (considered to be a weak acid) and a partition coefficient of 13.4, which signifies a partial solubility in both aqueous and hydrophobic media. Other structural characteristics of the molecule, respectively, the presence of the phenylacetic acid group and a phenyl ring that contain two chlorine atoms, facilitate the maximum torsion of the phenyl ring, a fact that ensures the proper binding coupling to cyclooxygenases (8, 9). It has a reduced oral bioavailability due to its poor solubility in water and in the gastric acid environment. It is eliminated 65% through the urine, has an enterohepatic circuit and is concentrated 35% in the bile. It has a relatively long duration of action (6-8 hours), but a half-life of 1.5-2 hours, which requires its administration in 3-4 daily doses (10).

Nanoparticles incorporating diclofenac sodium could represent innovative delivery systems with potential for prolonged action and lower side effects in rats, with advantages over use compared to the unincorporated drug.

MATERIAL AND METHODS

Substances

The test substance (diclofenac sodium) and those required for the preparation of

nanoparticles (chitosan, phosphatidylcholine, cholesterol, chloroform) were procured from Sigma-Aldrich Chemical Co., Germany (www.sigma-aldrich.com). The chitosan used had a degree of N-deacetylation of 79.7%, the average molecular weight was Mw = 310,000 g/mol and 3.26 polydispersity index. The 0.5% (w/w) chitosan solution was prepared in a 0.5% (v/v) acetic acid solution. The lipid used was L- α -phosphatidylcholine, type XVI-E, approximately 99% pure. Distilled water was obtained from Sicomed, Romania.

The preparation of lipid vesicles containing diclofenac

The lipid vesicles were prepared by dissolving the lipid in chloroform and removing the solvent by evaporation (11). The obtained dry lipid film was hydrated using a diclofenac solution in alcohol and the resulted solution was sonicated for 20 minutes. The lipid vesicles were mixed with the chitosan solution, which was thereafter dialyzed for 10 hours, to increase the pH to values close to the physiological ones.

To characterize the obtained particles by dimension and Zeta potential a Malvern Zetasizer Nano ZS ZEN-3500 apparatus (Worchestershire, UK) was used.

In vivo Experiments

For the experimental researches were used, 24 healthy, non-genetically modified white Wistar rats (3-month-old), weighing 200-250 g, with a uniform distribution by sex (half males, half females), which were purchased from the National Medical-Military Institute "Cantacuzino" for Research and Development, Băneasa Resort, Bucharest, Romania and brought to the CEMEX laboratory ("Advanced Center for Research and Development in Experimental Medicine - CEMEX") biobase, of the "Grigore T. Popa" University of Medicine and Pharmacy from Iasi.

The animals were kept under standard laboratory environment (relative humidity 55-65%, constant air temperature 23.0±2.0°C and 12 hours light: dark regimen). Before the experiment, rats were placed on a raised wire mesh, under a clear plastic box and allowed 2 hours to acclimate to the testing room.

The rats were fed fully with standardized solid specific food (pellets). The amount of food ingested by each animal was measured daily. Drinking water was administered *ad libitum*. In the days of the experiments, the animals were deprived of food and fluids. To prevent chronobiological influences, the tests were performed between 8-12 a.m. each day.

The laboratory animals were assigned into 3 groups of 5 rats each, which received the substances directly in the stomach (using an eso-gastric device), according to the following scheme:

- **Group 1 (Control):** distilled water 0.3 mL/100 g body - control;
- **Group 2 (DCF):** 5 mg/kg body weight (kbw) diclofenac sodium;
- **Group 3 (DCF-ves):** chitosan-based nanoparticles entrapping diclofenac sodium 5 mg/kbw;

The tail flick test (tail withdrawal test) is a thermoalgesic test that evaluates the reactivity to pain, by measuring the reaction time of animals whose tail is exposed to an infrared source of radiant energy, at a temperature of 50˚C (Tail flick Apparatus, UgoBasile, Pennsylvania, United States) which causes the tail withdrawal reaction. The response latency period is measured before (time zero) of the experiment, and 15 minutes, 30 minutes, 60 minutes, 90 minutes, 120 minutes, 4 hours, 6 hours, 8 hours, 10 hours and 12 hours after the ad-

ministration of the testing substance. The maximum allowed time (cut-off time) for each test is 12 seconds, to prevent damage to the biologic tissues (12, 13).

The results of the response to the tail flick test are expressed as mean values ± standard deviation of the mean (D.S.) of the latency time of the response to the painful thermal stimulus, at each time point and for each studied substance. To quantify the antinociception intensity, latencies are converted to percentages of the maximum possible effect (%EMP) according to the following formula:

%MPE = (observed latency – baseline latency) x100 / (cut of time – baseline latency) (14)

Changes in the pain threshold, obtained after the administration of the substances investigated, were considered relevant above 60% of EMP, because values below 60%, although may have statistical significance, the biological one is debatable.

The prolongation of the reaction time compared to the values obtained before and after the administration of the tested compounds or of the control group, corresponds to an antinociceptive effect. Shortening the latency of the response signify a hyperalgesic activity of the investigated substance (13).

The experimental protocol was approved (Certificate No. 24 / 21.12.2020) by the University Committee for Research and Ethical Issues, in compliance with the international ethical guidelines regarding the handling of laboratory animals (15, 16).

RESULTS

Soft matter lipid vesicles containing DCF, based on phosphatidylcholine and stabilized with chitosan were designed. The prepared DCF-ves were found to have a mean dimension of 562 nm and +45 mV mean Zeta potential, thus correspond to a relatively good stability of the solution.

The influence of DCF and the microvesicles containing DCF was evaluated in tail flick test, a standard somatic pain model in rodents.

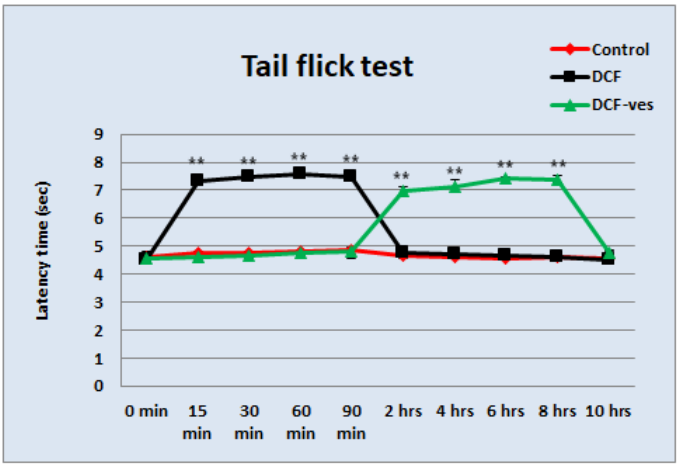

Fig. 1. The effects of DCF and DCF-ves in tail flick test in rats. Each point expresses the arithmetic mean ± SD of mean values for five animals in a group. The values of *p* coefficient (probability) **p<0.01 are considered statistically significant *versus* control.

Statistical analysis of data revealed that the probability associated with the calculated value of the Fisher test is higher (Sig. = 0.227) than the risk α=0.05, which means that there are no obvious differences between the three studied groups of animals at moment zero, respectively after 10 hours in tail flick test. No substantial variation of the latency time response to noxious thermal tail stimulation, at baseline, as well as at 10 hours, between the control, DCF and DCF-n groups.

The treatment with DCF was associated by a rapid and progressive prolongation of response latency period, statistically significant (**p<0.01) compared to the control group from 15 minutes (7.35±0.16 seconds) to 90 minutes (7.48±0.12 seconds) in this somatic pain model in rats. The longer latency time was observed at 60 minutes (7.58±0.12 seconds) after the beginning of the experiment. The obtained results are in accordance with the communicated data about the analgesic effect of this NSAID in tail flick test in rodents (17, 18).

The use of DCF-ves was associated with the lengthening of the latency period of the response to painful thermal tail stimulation, statistically significant (**p<0.01) compared to the control, in the interval between 2 hours (6.95±0.16 seconds) and 8 hours (7.40±0.11 seconds), in tail flick test in rat. The peak increase in the latency time was noted after 6 hours (7.45±0.05 seconds) in the experiment, after that, the nociceptive reactivity was gradually decreased to 8 hours.

Supplementary, %MPE, was used to assess the strength of antinociception, which represents an essential parameter to estimate the biological significance of the effects. The quantification of the intensity of the analgesic effect highlighted that the treatment with DCF resulted in an antinociceptive effect which was manifested immediately after administration of the substance, had a peak at 60 minutes (40.8±0.2 %EMP), and was maintained for 90 minutes (40.8±1.3 %EMP) in this cutaneous pain model in rats.

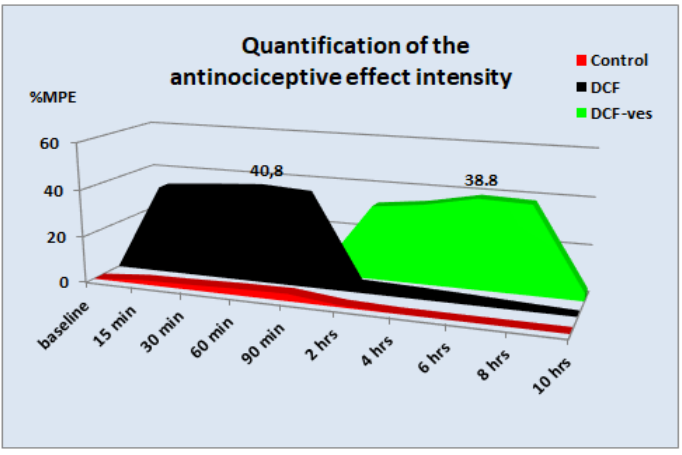

Fig. 2. Maximum possible effect (%MPE) produced by DCF and DCF-n in tail flick test in rats. Each point expresses the arithmetic mean ± S.D. of mean values for five animals in a group.

The use of DCF-ves resulted in a significant antinociceptive action, which started after a latency period of 120 minutes (32.0±1.7 %EMP) and lasted up to 8 hours (38.1±0.9 %EMP) in the experiment. The treatment with DCF-ves induced a %MPE (38.8±0.12) of analgesia at 6 hours in the experiment. The %EMP produced by DCF and DCF-ves were below 60% at any time of the determinations.

DISCUSSION

In the case of diclofenac sodium, it is a drug from the pharmacological class called non-steroidal anti-inflammatory drugs (NSAIDs) (19). Diclofenac sodium was developed to synthesize an NSAID with a high level of activity and good tolerability, having a percentage of hepatic metabolism of 50-52%. From an analgesic point of view, it is 6 times stronger than indomethacin, sulindac or codeine, 15 times stronger than naproxen and more than 40 times stronger than acetylsalicylic acid. It has low oral bioavailability due to its low solubility in water and in the gastric acid environment. It is eliminated in the proportion of 65% through the urine, has an enterohepatic circuit and is concentrated 35% in the bile. It has a relatively long duration of action (6-8 hours), but a half-life of 1.5-2 hours, which is why it needs to be administered in 3-4 daily doses (6).

In order to improve the pharmacokinetic profile, the pharmacodynamic effects and to reduce adverse effects, especially gastrointestinal, several types of nanoparticles with diclofenac were designed, using various materials including poly acid (lactide-co-glycolide); chitosan/poly methacrylic acid or polypyrrole/menthol; polyvinyl alcohol or didodecyldimethylammonium bromide (20-22).

Lipid-based formulations have been shown to significantly improve the bioavailability of hydrophobic drugs such as diclofenac compared to conventional dosage forms (23). The mucus covering the surface epithelium of the gastrointestinal tract possesses an adsorbent layer of phospholipids, which creates a hydrophobic zone between the epithelium and the luminal contents. At this level there are a number of lipid species reminiscent of surface-active phospholipids, of which phosphatidylcholine is suitable to incorporate diclofenac. It has been shown that in the presence of the ionic surfactant shield, the complex remains lipophilic (24).

Among all nanoparticulate systems, liposomes have a number of advantages, represented by the low number of excipients required for their formulation, the simple preparation procedure, a high physical stability and the possibility of sustained drug release, which could be used in the treatment of various pathological conditions (25).

Particulate systems such as micro- and nanoparticles contain an active principle in the core of the particle, which is called encapsulation. The purpose of encapsulation is to protect the unstable active ingredients, to achieve a modified, most often prolonged release, and to target the action of the active ingredients (24, 26).

Liposomes that efficiently incorporate diclofenac, based on chitosan of different molecular weights, were obtained using an ionotropic gelation method, formulations that were shown to have significant antibacterial activity (27).

We investigated the influence on the somatic cutaneous nociceptive reactivity of DCF and micro-particles containing DCF in tail withdrawal experimental model in rats. We proved that the use of both entrapped and non-entrapped DCF was accompanied by a considerable analgesic effect. The antinociceptive action of the non-entrapped

NSAID was evident in the first 90 minute, while the analgesic influence of micro-vesicles with DCF was manifested between 2 hours and 8 hours in this somatic pain model. The delayed appearance of the DCF-ves's pharmacodynamics effects can be attributed to the way in which the active substance is released from lipid micro-vesicles stabilized with chitosan.

Different studies have shown that the use of diclofenac sodium microsphere systems, based on sodium alginate, obtained by ionotropic gelation methods, improved the release profile of diclofenac, *in vitro* but also *in vivo* in the case of oral administration in healthy volunteers (28), while another study demonstrated a high degree of absorption of this anti-inflammatory incorporated into sodium alginate/ nanocrystal cellulose/polyvinyl alcohol microspheres functionalized with polyethyleneimine (29). Other researchers have prepared by a thin film hydration technique, wide lamellar vesicles of diclofenac sodium using soy lecithin, cholesterol and as solvents ethanol or a mixture of chloroform: methanol, but the effects in the laboratory animal have not been investigated (30-32). Another nanoparticle design consisted of encapsulating diclofenac sodium in phosphatidylcholine, cholesterol, stearyl amine and dicetylphosphate, through a lipid hydration technique (28). These liposomes have been well characterized, in vitro drug release has been described, but there are no data on the effects of this formulation system in laboratory animals.

CONCLUSIONS

Original micro-particles entrapping diclofenac with a mean size of 562 nm and a reasonable stability in suspension were prepared. The treatment with diclofenac incorporated and not incorporated in micro-vesicles produces significant analgesic effects in the laboratory animal in the tail flick test. The use of soft matter vesicles stabilized with chitosan as carriers for diclofenac presented the advantage of drug's sustained release, and a prolongation of the antinociceptive effects, comparing with non-entrapped substance in this somatic pain model in rats.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding the scientific research.

WHY ARE TEACHERS NOT ALWAYS WILLING TO FIGHT AGAINST CYBER-BULLYING? EXPLORING THE BELIEFS, ATTITUDES AND COPING STRATEGIES OF TEACHERS IN A MULTI-COUNTRY CROSS-SECTIONAL STUDY (Abstract): The increasing phenomenon of cyberbullying among adolescents in all countries needs preventive, educational, legal, and psycho-interventional measures. The present study **aimed** to identify the opinions of teachers about cyberbullying and their coping strategies. **Material and methods:** The study included 798 teachers from six countries (Italy, Portugal, Greece, Türkiye, Lithuania, and Romania). An online questionnaire was especially constructed for this research, gathering socio-demographic and job-related data along with information about teachers' opinions about the cyberbullying phenomenon, about victims and perpetrators, and their most frequent behaviors and coping strategies used to deal with the problem. The questionnaire also included 3 psychometric instruments. **Results:** The analysis of questionnaires revealed that even if only 38.5% of the teachers took a course on cyberbullying, more than 70% of them answered that they knew how to deal with cyberbullying. In teachers' opinions, cyberbullying occurs equally in boys and girls. The age 11-14 is the most exposed to bullying, while 15-18 is the most exposed to cyberbullying. More than 60% considered that students were responsible for bullying and cyberbullying. Age, gender, length of experience in the field of education, type of institution, and marital status influence cyberbullying perceptions and coping strategies. **Conclusions:** Personal beliefs and the occurrence of observed and reported incidents determine teachers' willingness to intervene in cyberbullying. The results are important for teachers and trainers to consider the teachers' role in analyzing both duties and barriers in fighting the cyberbullying phenomenon. **Keywords:** CYBERBULLYING, ADOLESCENT, VICTIM, PERPETRATOR, BYSTANDER, TEACHER, SCHOOL, COPING STRATEGIES.

Teaching is a noble profession that needs a powerful determination for life-long learning about science, skills, and communication techniques in order not only to transfer knowledge or to develop skills and capabilities but also to create emotion, build self-confidence, and stimulate curiosity in all kinds of students. Teachers enrich minds and souls, develop behaviors, form characters, and shape personalities. Involvement in the transformation and progress of students is inevitably accompanied by their own development.

The student–teacher trust relationship uniquely contributes to students' performance through school adjustment and academic motivation (1). Scholars discovered that a lack of trust between students and teachers, as well as feeling unsafe in school, increase the risk of mental health problems, traditional bullying, cyberbullying, various health problems, a low level of well-being and quality of life, and learning difficulties (2, 3). According to Wang and Degol (4) a safe school environment consists of three components: physical safety (reduced violence and aggression), emotional safety (lack of traditional bullying and psychological support and counseling), and order and discipline (school rules, conflict resolution, clarity, and fairness in decision making).

As a result, some studies have linked a deteriorating school climate to increased aggressive behavior among adolescents (5). Bullying, in all its forms, is an increasing phenomenon in all countries, especially in developed ones (6, 7, 8). Due to the increased use of the internet for academic tasks but also for communication, fun, social networking, or entertainment, the online bullying, also known as *cyberbullying*, has become a systemic public health issue (9) with a great impact on the physical, psychological, and social health of all those involved (victims, perpetrators, and bystanders). Cyberbullying rates worldwide vary from 2% to 56% and the "EU KIDS ONLINE" study of over 25,000 children between the ages of 9 and 16 reported a prevalence of cybervictimization ranging between 2 and 14%, the highest rates being found in Estonia and Romania and the lowest in Italy and Portugal (10) while Ortega and colleagues found a rate between 4 and 6.2% in Spain, Italy and UK (6, 7, 8).

Cyberbullying (CB) has been defined as an aggressive and deliberate behavior that is frequently repeated over time, carried out by a group or an individual using electronics and aimed at a victim who cannot defend himself/herself (11). The impact of cybervictimization has both short-term and long-term consequences, such as depression, anxiety, sleep-troubles, drop-off, suicide thoughts, self-isolation, and inconsistency in behavior (12-15). Due to its consequences on students' psychological, physical and social lives, and considering the negative impact on their academic performance, teachers are the key to solving bullying problems.

Reporting bullying behaviors to adults is crucial. According to Blomqvist *et al.* (16), being told about victimization was the best single predictor of teachers' intervention, frequently exceeding the effect of direct teachers' observations. Reports by victims are often teachers' only source of information about aggressive behaviors that take place in and outside the school environment. Bokkel *et al.* (17) mentioned that teachers are the only people to whom victimized students turn because of their proximity to all students (especially those hav-

ing difficult relationships with other adults, including parents) and their responsibility to create a safe classroom climate.

Data showed that when victimized students decide to tell someone about being bullied, they tend to tell friends rather than adults (16), and they tell parents more frequently than teachers (18,19). In fact, looking for help in school environments is low, and only 3-18% of the victims report the incidents to teachers. The decision to disclose to a teacher is a complex trade-off between potential costs and losses. First, they may be anxious that their situation will worsen when they tell their teacher (20). Further, students may be ashamed, convinced they will not be taken seriously or even be blamed by teachers for provoking or not standing up to victimization (21). In turn, teachers may misinterpret non-disclosure by a victimized student as the absence of a need for support, while the student might have that need. This begs the question to what extent teachers can facilitate disclosure. Cortes & Kochenderfer-Ladd (22) showed that punishing bullies can be associated with a lower likelihood of reporting to a teacher.

Teachers and other adults at school seemed to fail to recognize bullies, and the lack of identifying the victims led to a lack of appropriate intervention and encouraged bullying acts to continue. Blomqvist *et al.* (16) identified that the factors related to increased likelihood of telling an adult about cybervictimization were female gender, age, the chronicity of victimization, perceived negative teacher attitude towards bullying (teacher not tolerating bullying), and perceived peer support for victims (classmates' tendency to defend students who are victimized). Shaw (23) highlighted that talking about victimization was more likely among students who had been bullied for longer periods of time, with the result suggesting that when teachers found out about cyberbullying incidents after a considerable period of time, the students failed to stop the acts of aggression. When teachers do not intervene immediately, bullies may perceive an implicit consent to keep up their behavior (24). On the other hand, bystanders may feel less motivated to intervene with victims and report or blame the perpetrators (25). Therefore, a vicious circle is constructed and maintained.

All these aspects identified by a plethora of studies proved that dealing with cyberaggression and cybervictimization is a challenging task for teachers. The prevalence of cyberbullying involvement is largely inconsistent. Recent studies and meta-analyses indicated that bully prevention programs produce minimal change in student aggressive behavior and that there was a need for increased training for teachers on how to identify and combat cyberbullying (16, 23, 25). Despite the progress in cyberbullying research in recent years and the programs that were implemented in diverse countries, cyberbullying is still a challenging task for teachers. To cover the nowadays space, the aims of the study were: a) to identify the personal beliefs about this phenomenon among teachers and b) to identify the attitudes and strategies used to cope with cyberbullying among pre-university teachers in six countries and factors that influence them. Based on these, we assessed if there will be differences in what concern cyberbullying perception and strategies used to cope with cyberbullying considering the variables gender, number of children, marital status, length of experience, type of institution and experience with cyberbullying.

MATERIAL AND METHODS

Participants, eligibility criteria and informed consent

The study was approved by the Institutional Review Board No. 192/30.04.2022 of EuroEd School, Iasi, Romania. The questionnaire was distributed online simultaneously among teachers from six countries (Romania, Greece, Lithuania, Portugal, Italy, and Türkiye) in twenty-two middle and high schools from rural and urban areas between May 1st to June 30th, 2022.

To facilitate the approach of the group of teachers, invitations to complete the survey were sent by individual schools. The researchers first informed the principals of the schools regarding the study and the questionnaire was distributed to the teaching staff. Participants were informed online about the purpose of the study and ethical principles of the research (voluntary participation, protecting the confidentiality of data, the right to withdraw from the research at any time, being an *ERASMUS+* research and principal investigator contact). No incentive was given to the participants. After providing digital informed consent, participants were asked to complete the questionnaire.

The inclusion criteria were questionnaires filled in by teachers enrolled in private, public, or special schools, submitting fully filled in questionnaires before the deadline. The criteria for excluding questionnaires from the research were questionnaires not fully completed or submitted after the deadline. A total of 853 surveys were filled in. After excluding a number of 55, finally 798 questionnaires were included in the research. Figure 1 provides details on the response rate.

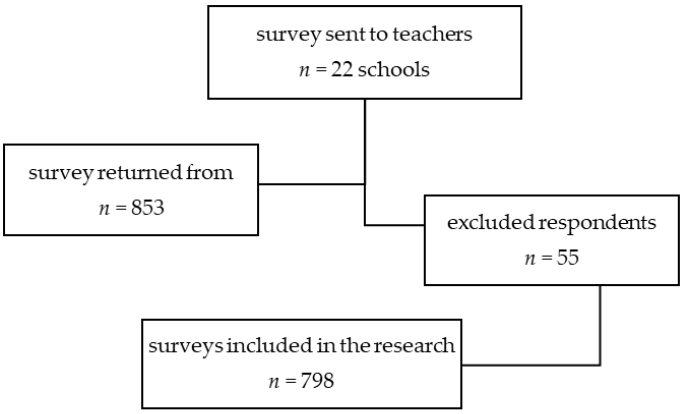

Fig. 1. Study profile.

Data collection and instruments

The questionnaire was constructed using the Google Forms application (Alphabet, Mountain View, CA, USA), was translated from English into all six national languages, and was developed to address the prevention, recognition, and intervention of online harassment against its cruel social, psychological, medical, and educational impact on adolescents.

a) The first section of the questionnaire collected socio-demographic information

(such as country, age, gender, marital status, number of kids, profession, length of experience, total number of years in teaching at their current school, and type of school where they teach).

b) The second part contained items about the teachers' opinions regarding the knowledge of bullying and cyberbullying behaviors, including their skills in recognizing the signs of bullying, preventing, and acting in such incidents among their students. Answers were registered with YES/NO or TRUE/FALSE about if they have taken anti-bullying courses; if they think that bullying is more common than cyberbullying; if they think that bullying and cyberbullying occur more frequently in the case of girls; if they teach students how to deal with bullying behaviors; and what they consider to be the age range at which bullying and cyberbullying occur most frequently.

c) The third part examines teachers' perceptions about cyberbullying by using a questionnaire developed by Li in 2009 (26). The instrument contains 22 items regarding perceptions about cyberbullying and about teachers' educational experiences in relation to cyberbullying. Responses to each item were indicated using a five-point Likert scale, with responses ranging from strongly disagree to strongly agree.

d) The fourth part of the survey collected information about teachers' views on the actions that teachers, parents, school principals, or even the Ministry of Education should take in order to prevent cyberbullying in schools. Participants also answered questions about those responsible for bullying or cyberbullying (students, parents, teachers, or the school) as well as the school's clear position on bullying, compliance or non-compliance against bullying, the impact of cyberbullying on students, and how teachers or the school principal intervene in cases of observing such behaviors. In addition, teachers were asked whether they agreed that students were exaggerating about cyberbullying behaviors, whether students should manage bullying and cyberbullying on their own, and whether they were confident that they could recognize and manage bullying and cyberbullying situations. Self-assessed items were constructed, and responses were assessed on a 5-point Likert scale.

e) In the next section, respondents were asked to tick the number that best matches the following statements (on a Likert scale from 1 to 5, where 1 = never and 5 = always): requesting a discussion with parents when it comes to issues related to cyberbullying among students, sending students to the principal when it comes to cyberbullying, or not involving teachers in these issues. Respondents continued to answer YES/NO to questions about rumors that students were harassing each other during or outside class; if cyberbullying intensified among teenagers; if some students even complained to teachers about the situations of cyberbullying in which they had taken part, if the teachers knew of students who were harassing or had been harassed online; if parents, the school principal, or the school counsellor were informed; if teachers were told or even witnessed bullying behavior; and not least if teachers considered that cyberbullying could be reduced by prevention or intervention.

f) The sixth section includes questions about the frequency of bullying and cyberbullying behaviors observed or reported by others among students, and how often teachers intervened to discipline or

counsel students during this behavior. Answers range on a Likert scale from 1 (several times a day) to 7 (never). In addition, some questions were raised about the risks that some children had (obese, mentally ill, with physical syndromes, those with a single parent, those with a precarious economic situation, introverts, those with a high or low level of intelligence, or those with poor school results) could be subjected to cyberbullying. Answers range on a Likert scale from 1 (very low risk) to 5 (very high risk).

g) The final part of the questionnaire addressed two psychometric instruments used to identify the ways teachers succeeded in perceiving cyberbullying problems and to identify what kinds of strategies they usually used in order to deal with this phenomenon among their students:

The *Teacher Cyberbullying Perception Scale* (TCPS) is a 14-item scale which was created by Ayas and Horzum in 2011 (27) to determine how well teachers perceived the problems of cyberbullying among their students. A 5-point Likert-type rating was used to express the level of agreement with the items on the scale. This rating is: always (5), often (4), sometimes (3), rarely (2), and never (1).

The *Strategies for Coping with Cyberbullying Scale for Teachers* (SSBCS) was created in 2018 by Altundag and Ayas (28). It is a measurement tool for the coping strategies of teachers often witnessing cyberbullying events experienced by adolescents. The measurement tool consists of two sub-domains, the 'knowledge area' and the 'application area'. The scale was prepared in a five-point Likert type, with responses ranging from 1 (strongly disagree) to 5 (strongly agree). High scores on both the knowledge and application areas of the scale indicated the high level of teachers' perceptions of cyberbullying coping strategies.

Statistical analysis

All analyses for this research were performed using IBM *Statistical Package for Social Sciences* (*SPSS*) Statistics for Windows, version 29 (SPSS Inc., Chicago, IL, USA). Results for descriptive statistics were expressed as means and standard deviations (SD).

The normality of data distribution was assessed by using the Kolmogorov-Smirnoff test. Given the fact that all data points are not normally distributed, bivariate analysis will be performed and non-parametric tests will be applied.

To assess comparative results considering gender, profession, and taking anti-bullying classes, the Mann-Whitney test was performed. Similarly, comparative results considering country, marital status, the number of children from a household, and the type of school where the respondents teach were assessed using the Kruskal-Wallis H test to determine if there were statistically significant differences between more of two groups of an independent variable on a continuous or ordinal dependent variable.

The Spearman correlation was used to assess the relationship between variables. A p-value < 0.05 was considered statistically significant.

RESULTS

Socio-demographic data, family characteristics, professional details

Teachers included in the research were from six different countries: Romania (n = 343, 43.0%), Türkiye (n = 197, 24.7%), Portugal (n = 94, 11.8%), Greece (n = 59,

7.4%), Lithuania (n = 59, 7.4%), and Italy (n = 46, 5.77%). More than half of the participants were married (n = 556, 69.7%) and had an average of M = 1.35 ± 0.97 children.

The mean age of the teachers participating in the study was M = 46.90 ± 9.66 with a minimum of 20 and a maximum of 68 years old, more than 3/4 being women (76.47%). The results of the study showed that the participants had practiced their profession for an average of 21.29 ± 10.76 years. In the school where the respondents now teach, they had been within the department for M = 11.19 ± 9.46 years.

Most of the respondents included in the study were teachers (n = 753, 94.4%) and very few were school counselors (n = 45, 5.6%). Moreover, most teachers worked in public schools (n = 718, 90.0%).

Teachers' opinion about the age and gender of students who are more prone to experiencing cyberbullying.

More than half of the teachers had never taken anti-bullying courses (n = 491, 61.5%). However, more than half of the teachers considered that they knew how to deal with cyberbullying (n = 560, 70.2%).

More than half of the teachers believed that bullying occurred more often than cyberbullying (n = 509, 63.8%), and a similar percentage believed that bullying (n = 499, 62.5%) and cyberbullying (n = 502, 62.9%) did not occur more frequently in girls.

Moreover, more than half of the teachers pointed out that the age most prone to bullying is between 11-14 years old (n = 489, 61.3%), followed by the categories of 15-18 (n = 252, 31.6%) and 6-10 years old (n = 57, 7.1%), while in terms of cyberbullying, the most exposed age categories are approximately equal: 15-18 (n = 405, 50.8%) and 11-14 (n = 367, 46.0%) years old**.**

Teachers' perceptions of cyberbullying

The third part of the research focused on teachers' perceptions of cyberbullying and their educational experiences in relation to cyberbullying. Answers for each perception item were indicated using a five-point Likert scale, with responses ranging from 1 (strong disagreement) to 5 (strong agreement). The Alpha coefficient of the internal reliability of the instrument was 0.90.

The majority of the teachers also agreed that they were concerned about cyberbullying. Data analysis showed that only a quarter of the teachers thought that cyberbullying was a problem in schools, while less than half held neutral positions. When asked if the children were affected by cyberbullying, the pattern changed. Approximately 65% of the teachers agreed that cyberbullying affected children. Regarding teachers' confidence in approaching cyberbullying, it was found that about half of them had confidence in both identifying and managing cyberbullying issues with a gender difference (teachers' confidence in approaching cyber-bullying.

Teachers' beliefs about the importance of school engagement were examined and were broadly defined to include aspects from school policy and classroom strategies to school activities. Thus, the results showed that more than 75% of the participants agreed that all these strategies should be addressed to prevent or deal with the problem of cyber harassment.

Finally, the questionnaire aimed to find out how prepared the teachers were to

manage bullying and cyberbullying incidents. The responses showed that less than half of the teachers felt that their current university education did not prepare them to deal with cyberbullying, and more than half of them wanted to spend more time studying to learn more about cyberbullying. Detailed results regarding the answers to the mentioned items are presented in first table.

TABLE I.
Teachers' perceptions about cyberbullying[1]

ITEMS	Disagree or strongly disagree	Neutral	Agree or strongly agree
Problems in schools	255 (32.0)	334 (41.9)	209 (26.2)
Children are affected	112 (14.1)	166 (20.8)	520 (65.2)
Teachers are concerned	49 (6.1)	144 (18)	605 (75.8)
Identifying cyberbullying	93 (11.7)	216 (27.1)	487 (61)
Managing cyberbullying	13, (17.5)	281 (35.2)	378 (47.4)
Schools' policies	30, (3.8)	97 (12.2)	670 (84)
Training teachers	34 (4.3)	69 (8.6)	695 (87.1)
Curriculum	54 (6.8)	134 (16.8)	609 (76.3)
Classroom activities	4 (5.3)	113 (14.2)	643 (80.6)
School-wide activities	31 (3.9)	79 (9.9)	688 (86.2)
Discussing with parents	29 (3.7)	87 (10.9)	681 (85.3)
University prepares teachers	350 (43.9)	183 (22.9)	263 (32.9)
Teachers want to learn more	110 (13.8)	189 (23.7)	498 (62.4)

*[1]Number (n) and percentages (%).

Scale results for teachers' perceptions of cyberbullying and their educational experiences in relation to cyberbullying ranged from 27 to 109 ($M = 84.05 \pm 10.47$).

The Mann-Whitney U test revealed significant gender differences ($U = 47726.50$, $Z = -2.975$, $p = 0.003$), with men ($Mdn = 83.00$) scoring lower on the scale that measures teachers' educational experiences in relation to cyberbullying than women ($Mdn = 85.00$) but higher regarding the confidence in approaching cyberbullying ($U = 48590{,}000$, $Z = -3.222$, $p = 0.001$), showing that male teachers ($Md = 4$) were more confident than women ($Md = 3$).

Significant differences were found regarding the type of institution in which teachers work ($U = 19710.00$, $Z = -3.837$, $p < 0.001$) in the sense that teachers from public schools ($Mdn = 85.00$) had higher scores on this scale compared to teachers from private schools ($Mdn = 81.00$). Additionally, a Mann-Whitney U test revealed significant differences in terms of participants' marital status ($U = 3572.50$, $Z = -2.630$, $p = 0.009$) in the sense that married teachers ($Mdn = 84.00$) had higher scores on the scale which measured teachers' perceptions and educational experiences in

relation to cyberbullying than single teachers (Mdn = 78.00).

A Kruskal-Wallis test was conducted to determine if there were differences in these scale scores among teachers between countries of origin. As assessed by visual inspection of a boxplot, the distributions of these scale scores were not similar for all groups. Median scores were statistically significantly different between the countries, $\chi^2(5) = 94.528$, $p < 0.001$. A pairwise comparison method was performed using Dunn's (1964) procedure with a Bonferroni correction for multiple comparisons. Adjusted *p*-values are presented. This post hoc analysis revealed statistically significant differences in median scores of this scale between: Romania (85.00) and Lithuania (81.00) ($p = 0.002$), Romania (85.00) and Greece (70.00) ($p < 0.001$), Romania (85.00) and Portugal (89.00) ($p = 0.003$), Greece (70.00) and Portugal (89.00) ($p < 0.001$), Greece (70.00) and Italy (86.00) ($p < 0.001$), Portugal (89.00) and Lithuania (81.00) ($p < 0.001$), Portugal (89.00) and Türkiye (83.00) ($p < 0.001$), Italy (86.00) and Türkiye (81.00) (p = 0.015), Lithuania (81.00) and Italy (30.00) (p = 0.012), Türkiye (81.00) and Greece (70.00) ($p < 0.001$), Türkiye (81.00) and Romania (85.00) ($p < 0.001$).

The opinions of teachers Regarding the institutions or responsible that should take attitude in preventing cyberbullying

More than half of the participants agreed that teachers (56.9%, n = 454), parents (53.1%, n = 424), school principals (54.3%, n = 433), and the Ministry of Education (50.9%, n = 406) should do more to prevent cyberbullying. Furthermore, more than half of the teachers (60.3%, n = 481) agreed and strongly agreed that students were responsible for bullying and cyberbullying. Additionally, more than half of the teachers agreed that parents and the school were responsible for tackling cyberbullying inside the school. Detailed results are presented in second table.

TABLE II.
Responsibility of cyberbullying[1]

The most responsible for cyberbullying phenomenon	Disagree or strongly disagree	Neutral	Agree or strongly agree
Teachers	266 (33.3)	242 (30.3)	290 (36.4)
Parents	208 (26)	242 (30.3)	347 (65.2)
School	162 (20.3)	219 (27.4)	416 (52.1)

*[1]Number (n) and percentages (%).

Teachers were asked to express their opinion regarding the schools' rules established against bullying and cyberbullying, and most of them considered that these rules were followed. When it comes to the impact of cyberbullying on students, most teachers believed that there was a negative impact of cyberbullying such as depression and poor academic performance.

Most teachers stated that they agreed (51.8%, n = 413) and totally agreed (36.7%, n = 293) to intervene if they noticed aggression among students. They declared that the school principal approved of the teacher's decision to act in cases of cyberbullying of students (agree: 53.0%, n = 423; totally agree: 17.5%, n = 140). Most of them stated that they agreed (50.6%, n = 404) and totally agreed (21.9%, n = 175) that it was their duty to intervene in any

incidents of cyber aggression among their students. The analysis of answers revealed that more than half of the teachers did not agree that these conflicts prepared students for life, or that victims should manage these situations on their own. Table III presents the detailed results regarding the teachers' answers to the mentioned items.

TABLE III.
Results regarding the teachers' answers

ITEMS	Disagree or strongly disagree	Neutral	Agree or strongly agree	M ± SD
Non-compliance with school rules regarding bullying	376 (47.2)	244 (30.6)	177 (22.1)	2.64 ± 1.04
Non-compliance with school rules regarding cyberbullying	46 (57.7)	243 (30.5)	93 (11.7)	3.67 ± 0.85
Negative impact of cyberbullying	134 (16.8)	85 (10.7)	576 (72.2)	3.88 ± 1.12
Cyberbullying causes depression in students	20 (2.5)	82 (10.3)	694 (87)	4.16 ± 0.72
Cyberbullying causes poor academic results in students	28 (3.5)	127 (15.9)	64 (80.5)	4.03 ± 0.77
Students exaggerate cyber aggression	292 (36.6)	321 (40.2)	185 (23.2)	2.80 ± 1.09
Cyberbullying prepares students for life	63 (79.4)	97 (12.2)	68 (9.5)	1.75 ± 1.09
Students should handle bullying situations on their own	594 (74.5)	136 (17)	68 (8.5)	2.10 ± 0.90
Students should handle cyberbullying situations on their own	513 (64.3)	152 (19)	132 (16.5)	2.32 ± 1.03

[1]Number (n), percentages (%), and means and standard deviations (M ± SD).

Self-evaluation about the attitudes and behaviors in case of bullying and cyberbullying incidents

In general, most teachers believed that the phenomenon of cyberbullying was intensifying among adolescents and that this phenomenon could be eradicated by both intervention and prevention. A series of items were used to evaluate the attitude of teachers in the event of being told about an incident. The analysis of answers revealed that more than a third of the teachers (37.6%, n = 300) said they sent students to the principal for cyberbullying problems only occasionally. Also, in more than a third of cases (38.2%, n = 305), teachers always asked for a discussion with their parents when it came to cyberbullying among students. In similar percentages (35.2%, n = 281), respondents said they never agreed with the non-involvement of students' cyberbullying.

The data gathered showed that few students reported bullying events to teachers as victims (whether they had been the subject of malicious gossip, received malicious messages, their identity had been stolen etc.). Instead, most teachers reported any events they attended or heard about to parents (tab. IV).

TABLE IV.

Self-rated items regarding teachers' behavior in case of bullying events[1].

ITEMS	YES	NO
I was told that students harass each other online during class	161 (20.2)	636 (79.7)
I was told that students harass each other online after class	271 (34)	527 (66)
I think that the phenomenon of cyberbullying is intensifying among teenagers	69 (**86.6**)	106 (13.3)
The students complained directly to me that they had received malicious text messages on the phone about themselves	240 (30.1)	552 (69.2)
The students directly complained to me that they had been the subject of online rumors.	224 (28.1)	573 (71.8)
My students complained directly about receiving malicious/threatening emails/messages.	167 (20.9)	630 (**78.9**)
My students complained directly that someone had hijacked their identity online	116 (14.5)	682 (**85.5**)
I know students who are cyber-harassed by others	237 (29.7)	561 (70.3)
I know students who cyberbully other students in my school	152 (19)	645 (**80.8**)
I always inform parents about an incident of aggression that I witness	634 (**79.4**)	162 (20.3)
I always inform parents about an aggression incident of which I am informed	629 (**78.8**)	168 (21.1)
I believe that the phenomenon of cyberbullying can be mitigated by prevention	720 (**90.2**)	78 (9.8)
I believe that the phenomenon of cyber harassment can be mitigated by intervention	721(**90.4**)	74 (9.3)

*[1]Number of answers (N) and percentage (%).

Frequency of bullying behaviors and typology of victims

Teachers were asked what their views were on how exposed certain children were to becoming victims of cyberbullying. The results showed that children with mental illness (34.2%, n = 273), obesity (30.6%, n = 244), physical syndromes (31.2%, n = 249), and introverted children (31.3%, n = 250) were at a very high risk of becoming victims. On a Likert scale from 1 to 7, where: 1 = several times a day, 2 = once a day, 3 = once a week, 4 = once a month, 5 = once every few months, 6 = once a year or once every few years 7 = never, the analysis of the responses revealed that teachers did not see or report bullying behaviors in school very frequently. In addition, in very few cases, teachers did not intervene to discipline or counsel during the bullying or cyberbullying process. The distribution of the answers is presented in table V.

TABLE V.
Self-rated items regarding teachers' behavior in case of bullying events[1.]

ITEMS	1	2	3	4	5	6	7	M ± SD
How often have you directly noticed aggressive behavior in your school?	57 (7.1)	58 (7.3)	139 (17.4)	101 (12.7)	172 (21.6)	130 (16.3)	141 (17.7)	4.54 ± 1.81
How often have you been told about aggressive behavior in your school?	42 (5.3)	49 (6.1)	140 (17.5)	142 (17.8)	176 (22.1)	147 (18.4)	102 (12.8)	4.52 ± 1.65
To what extent did you personally intervene to discipline, send, or counsel during the assault process?	21 (2.6)	49 (4.9)	86 (10.8)	97 (12.2)	176 (22.1)	186 (23)	192 (24.1)	5.13 ± 1.61
To what extent did you personally intervene to discipline, support, or counsel during the cyberbullying process?	9 (1.1)	21 (2.6)	75 (9)	71 (8.9)	149 (18.7)	151 (18.9)	320 (40.1)	5.59 ± 1.52

*[1]Number of answers (N) and percentage (%).

Teacher Cyberbullying Perception Scale (TCPS)

The global cyberbullying perception scores of teachers as measured with the TCPS ranged from 15 up to 67 (M = 28.09 ± 7.14). For the present study, the Cronbach Alpha score was 0.822. There are significant differences on this scale in terms of participants' gender (U = 45357,500, Z = -4.203, $p < 0.001$) in the sense that women had a lower score on cyberbullying perception (Mdn = 26.00) compared to men (Mdn = 30.00).

A Kruskal-Wallis test was conducted to determine if there were differences in *TCPS* scores among teachers between countries of origin: Italy (N = 46), Greece (N = 59), Lithuania (N = 59), Portugal (N = 94), Romania (N = 343), and Türkiye (N = 197). As assessed by visual inspection of a boxplot, the distributions of these scale scores were not similar for all groups. Median Cyberbullying Perception scores were statistically significantly different between the countries, $\chi2(5) = 151.254$, $p < 0.001$. Subsequently, pairwise comparisons were performed using Dunn's (1964) procedure with a Bonferroni correction for multiple comparisons. Adjusted p-values are presented. This post hoc analysis revealed statistically significant differences in median TCPS scores between: Romania (25.00) and Lithuania (28.00) ($p < 0.001$), Romania (25.00) and Greece (37.00) ($p < 0.001$), Greece (37.00) and Italy (27.00) ($p < 0.001$), Greece (37.00) and Lithuania (28.00) ($p < 0.001$), Portugal (25.00) and Greece (37.00) ($p < 0.001$), Portugal (25.00) and Türkiye (30.00) ($p < 0.001$), Italy (27.00) and Türkiye (30.00) ($p = 0.006$), Lithuania (28.00) and Türkiye (30.00) ($p = 0.008$), Türkiye (30.00) and Greece (37.00) ($p < 0.001$), and Türkiye (30.00) and Romania (25.00) ($p < 0.001$).

A Kruskal-Wallis test was conducted to determine if there were differences in *Cyberbullying Perception* scores among teachers between the numbers of children: none (n = 179), one kid (n = 252), two kids (n = 296), three kids (n = 57), four kids (n = 11) or more than four children (n = 3). As assessed by visual inspection of a boxplot, the distributions of these scale scores were not similar for all groups. Median *TCPS*

scores were statistically significantly different between the mentioned categories, $\chi 2(5) = 15.339$, $p = 0.009$. Post hoc Mann Whitney analysis showed that teachers who had no children ($U = 3933.50$, $Z = -2.605$, $p = 0.009$, $Mdn = 26.00$) or only one child ($U = 4959.50$, $Z = -3.654$, $p < 0.001$, $Mdn = 26.00$) had a lower score on the *Perception of Cyberbullying Scale* compared to teachers who had three children ($Mdn = 30.00$).

A Kruskal-Wallis test was conducted to determine if there were differences in the *Teacher Cyberbullying Perception* scores between types of institutions in which teachers work: public schools (n = 718), private schools (n = 76), and special schools (n = 3). As assessed by visual inspection of a boxplot, the distributions of these scale scores were not similar for all groups. Median Cyberbullying Perception scores were statistically significantly different between the mentioned categories, $\chi 2(2) = 32.213$, $p < 0.001$.

Post hoc Mann-Whitney analyses showed that teachers who worked in a public school ($U = 17240.50$, $Z = -5.288$, $p < 0.001$, $Mdn = 27.00$) had a lower score on the scale of perception of cyberbullying compared to those who worked in a private school ($Mdn = 32.50$), while teachers in both public ($U = 23.500$, $Z = -2.930$, $p = 0.003$) and private schools ($U = 16.000$, $Z = -2.516$, $p = 0.005$) had a lower score on the scale of perception of cyberbullying, compared to teachers working in special schools ($Mdn = 49.00$).

Strategies for Coping with the Cyber bullying Scale for Teachers (SSBCS)

The total score for the SSBCS scale was on average $M = 144.47 \pm 18.68$, scores ranging from 36 (0.1%, N = 1) to 180 (0.8%, N = 6). The Cronbach Alpha score was 0.944.

There are significant differences on this scale in terms of participants' gender ($U = 46782.50$, $Z = -3.682$, $p < 0.001$), in the sense that women had a higher score on the SSBCS scale ($Mdn = 147.00$) compared to men ($Mdn = 143.00$). Additionally, the Mann-Whitney U test ($U = 15339.00$, $Z = -6.284$, $p < 0.001$) showed that there was a significant difference on this scale between the types of institutions in which teachers worked, meaning that teachers from private institutions ($Mdn = 81.00$) had lower scores on this scale than teachers from public schools ($Mdn = 85.00$).

A Kruskal-Wallis test was conducted to determine if there were differences in these scale scores among teachers' marital status: unmarried (n = 146), in a relationship (n = 76), married (n = 556), or widowed (n = 20). As assessed by visual inspection of a boxplot, the distributions of these scale scores were not similar for all groups. Median scores were statistically significantly different between these categories, $\chi^2(3) = 13.124$, $p = 0.004$. A Mann-Whitney U post hoc test ($U = 16861.50$, $Z = -2.858$, $p = 0.004$) revealed that married teachers ($Mdn = 147.00$) had higher scores than teachers who were in a relationship ($Mdn = 143.00$) on the scale which measured teachers' coping strategies for perceptions cyberbullying. Furthermore, another Mann-Whitney U post hoc test ($U = 3779.50$, $Z = -2.436$, $p = 0.015$) showed that married teachers ($Mdn = 147.00$) had higher scores on this scale compared to single teachers ($Mdn = 136.50$).

A Kruskal-Wallis test was also conducted to determine if there were differences in SSBCS scores among teachers between countries of origin. As assessed by visual inspection of a boxplot, the distributions of these scale scores were not similar for all groups. The Median SSBCS scores

were statistically significantly different between countries, $\chi^2(5) = 162.178$, $p < 0.001$. Subsequently, results of post hoc analysis revealed statistically significant differences in median SSBCS scores between: Romania (149.00) and Greece (108.00) ($p < 0.001$), Romania (149.00) and Italy (143.00) ($p < 0.001$), Romania (149.00) and Lithuania (136.00) ($p < 0.001$), Greece (108.00) and Portugal (147.50) ($p < 0.001$), Greece (108.00) and Lithuania (136.00) ($p < 0.001$), Portugal (147.50) and Lithuania (136.00) ($p < 0.001$), Portugal (147.50) and Romania (149.00) ($p = 0.020$), Italy (143.00) and Greece (108.00) ($p < 0.001$), Italy (143.00) and Lithuania (136.00) ($p = 0.022$), Lithuania (136.00) and Türkiye (149.00) ($p < 0.001$), Türkiye (149.00) and Greece (108.00) ($p < 0.001$), Türkiye (149.00) and Italy (143.00) ($p < 0.001$).

Correlation analysis

The results of the Spearman correlation analysis showed that there were negative correlations between the total number of years the teachers had been practicing, as well as their beliefs that the phenomenon of cyberbullying was on the rise among adolescents ($r = -0.579$, $p < 0.001$) and their perception of cyberbullying ($r = -0.092$, $p = 0.010$), in the sense that the higher the number of years in education and the higher the teachers' beliefs that cyberbullying was rising, the lower the teachers' perception regarding cyberbullying. There are also negative correlations between the TCPS scale and the SSCBS scale ($r = -0.442$, $p < 0.001$) in the sense that as teachers' perceptions of cyberbullying increase, the teachers' coping strategies regarding cyberbullying decrease.

The total number of years that teachers worked correlates positively with the scale of teachers' coping strategies in terms of cyberbullying ($r = 0.074$, $p = 0.036$), in the sense that the higher the number of years worked, the higher the score on the SSCBS scale. Furthermore, there is a negative correlation between teachers' beliefs that the phenomenon of cyberbullying is on the rise among adolescents and the SSCBS scale ($r = -0.159$, $p < 0.001$), in the sense that the higher the teachers' beliefs that cyberbullying is rising, the lower the teachers' coping strategies regarding cyberbullying.

Both positive and negative correlations were identified between teachers' views of those responsible for cyberbullying, the main factors that could prevent cyberbullying, its negative effects, and the number of children in the teachers' families, the number of years they had been practicing, their faith in the fact that cyberbullying is becoming more prevalent among teenagers and the TCPS and SSCBS scales (tab. VI).

Strong positive correlations were identified between age ($r = 0{,}144$, $p < 0.001$), the total number of years of experience in the education field ($r = 0{,}135$, $p < 0.001$), teachers' perceptions of cyberbullying ($r = 0.122$, $p = 0.001$), and the frequency with which teachers had observed aggressive behavior in their school, in the sense that the older the teachers, the more experience they had and the more increased perception of cyberbullying, the more often they observed aggressive behaviors in school, and the more sensitive and empathic they were.

Some other variables, such as age ($r = 0.094$, $p = 0.008$), the total number of years teachers had been working ($r = 0.110$, $p = 0.002$), and the scale of coping strategies for cyberbullying ($r = 0.158$, $p < 0.001$) correlated positively with the frequency of observing aggressive online behaviors. Other significant and relevant correlations are presented in table VII.

TABLE VI.

Correlational results of teachers' views on the actors that could prevent cyberbullying[1]

ITEMS	Parental status (no. of kids)	Length of experience in the field	Cyber-bullying is a growing phenomenon	TCPS scale	SSCBS scale
I think I should do more to prevent cyber-bullying	no correlation	no correlation	r = -0.192 p < 0.001	r = -0.332 p < 0.001	r = 0.296 p < 0.001

DISCUSSION

Most of the teachers included in the research (86.6%) sustained that cyberbullying was an increasing phenomenon among adolescents. Even if there was a worrying perception about this problem, only 38.5% of the teachers had taken a course on cyberbullying. Less than three quarters of the teachers answered that they knew how to deal with cyberbullying, but it is evident from the analyze of the answers that even if one third of them had taken a course about cyberbullying, twice as many teachers rated themselves as capable of handling it. Less than half of the teachers felt that their current university education had not prepared them to deal with cyberbullying, and more than half of them wanted to spend more time studying more about cyberbullying. Our data are consistent with those presented by scientific literature. For example, the Dutch teachers included in a study conducted by Oldenburg *et al*. (29) gave incomplete definitions of bullying. The authors identified that respondents had limited strategies to find out about bullying, and many of them never recognized the self-reported victims in their classroom. These extremely important results suggested by some research on teachers revealed that, even if teachers have a central role in tackling bullying, they are not always fully trained for this task. Similar results were found in a study conducted by Khanolainen *et al.* (30). The research identified that the majority of the teachers indicated either seeing no bullying or only seeing bullying rarely as a justifiable reaction to provocation, while their students reported that bullying and cyberbullying incidents were quite frequent in their school and sustained that "teachers are seeing nothing".

It is important to separate the skill of identifying bullying and cyberbullying incidents in general and the willingness to do it. Rigby and his team (31, 32) found that a large proportion of adolescent girls (43.0%) and boys (51.4%) were not confident in teachers' ability to respond effectively. Shaw *et al* (23) found that if students perceived that teachers were unlikely to intervene or that the school climate was tolerant of bullying, they would be less likely to disclose that they were being vic-

timized.

A sequence of items investigated teachers' sensitivity to the phenomenon. In total, 20% of the teachers sustained that they were informed about cyberbullying in school and 34% of them about cyberbullying incidents outside of school. Considering the gender of their students and cyberbullying victimization, respondents appreciated that cyberbullying occurred equally in boys and girls, and more than 60% considered that students were the main ones responsible for bullying and cyberbullying incidents. In their opinion, the age 11-14 was the most exposed to bullying, while 15-18 was the most exposed to cyberbullying. Age (more frequent, the older teachers were more prone to being sensitive to victimization), gender (more women than men), length of experience in the field of education (experienced teachers were more prone to identify victimization), type of institution (teachers from public schools were more sensitive to cyberbullying than teachers from private schools), and marital status (married teachers and those who had children) were influencing cyberbullying perceptions and the coping strategies that they used in order to solve cyberbullying incidents. Similar findings were identified by Yilmaz (20) Yildirim *et al*. (33) who suggested that married teachers had a higher level of cyberbullying sensitivity.

The key to success in the elimination of cyberbullying and its negative effects lies in school policies, parental support, and cyberbullying sensitivity, the last one being the most important tool for teachers. Our study identified that age, length of experience, and a high level of perception of cyberbullying were related to a high level of identifying aggressive behavior in school. Furthermore, women obtained higher scores on the scale that measured teachers' educational experience than men. We noticed that married teachers had higher scores on the scale which measured teachers' coping strategies for perceptions of cyberbullying than teachers who were not married yet, and the same when compared to single teachers. This variable was mentioned in some studies focusing on teachers' perception of cyberbullying. For example, Yildirim *et al.* (33) sustained that it can be suggested that married teachers had a higher level of cyberbullying sensitivity, and that analyzing teachers' cyberbullying, and cyber victimization experiences should be related to cyber sensitivity. The authors identified that teachers who had an undergraduate degree had a higher level of cyberbullying sensitivity. As Eden *et al.* also identified, female teachers were found to express more concern than male teachers, as did teachers of younger children.

Our study identified that teachers appreciated that children with mental illness, obesity, diverse physical syndromes, and introverted kids are at a very high risk of becoming victims. These results are congruent with data obtained by Zhu, (34) Olenik-Shemesh *et al.* (14), Bokkel (17) and Fossum (33). Evaluating all the risky variables identified by the scientific literature, the most common are, of course, the variables that are easily identified by direct observation. But some other characteristics of the students must not be neglected, and preconceptions should guide the interventions in the case of cyberbullying with precociousness. For example, some authors (30-32) maintain that even popular students or students with high academic grades are victims of cyberbullying, but usually they do not share this in order not to be seen as week or to lose their status in school or class. Moreover, mentally ill students and

lonely ones usually do not share in order not to be more severely aggressed by the persecutor. Considering the small percentage of teachers that are being told about, we can consider that these answers are the results of their experience with reporting incidents or of their preconceptions (opinions) regarding the type of the victims. The students who were identified as being more vulnerable to victimization need more attentive care and permanent supervision, in general, due to their mental, physical, or emotional condition.

The current research also highlights some dilemmatic results. We identified that the higher the number of years in education and the higher the teachers' beliefs that cyberbullying is rising, the lower the teachers' perception regarding cyberbullying. There were also negative correlations between the TCPS scale and the SSCBS scale, meaning that as teachers' perceptions of cyberbullying increased, the teachers' coping strategies regarding cyberbullying decreased. Additionally, the length of experience in the field positively correlated with the score on the Scale of Teachers' Coping Strategies, in the sense that the higher the number of years worked, the higher the score on the SSCBS scale. Furthermore, the higher the teachers' beliefs that cyberbullying is rising, the lower the teachers' coping strategies regarding cyberbullying. These results could be sustained by the fact that respondents realized that cyberbullying is increasing extremely rapidly, and there is no possibility to fight by themselves, or the phenomenon that is spreading becomes normality in the school environment.

The results identified by this study and that can also be seen in some other published research led to a general, common idea that teachers did not invest time and effort in countering the phenomenon of bullying and cyberbullying and were not always willing to get involved in mediation between the victim-aggressor-witnesses (30-32).

Many of the teachers declared that bullying, in all its forms, prepared students for adult life, although a large part of them admitted that there were important negative consequences on the physical and mental health, as well as the academic results of the victim, with a long-term impact even in adult life.

The first explanation would be the lack of training programs. Teachers must be trained in how to identify, analyze, behave, intervene, and constructively manage the bullying phenomenon in their classes, and how to help the victim, perpetrator, and bystander. Studies have shown that students lose confidence if the first reported incident is not resolved conveniently. Additionally, the literature presents studies that explain the way in which the victim reaches the aggressor's turn in order to defend themselves, and the active spot witnesses are also considered aggressors (30-32). Passivity in the case of bullying and cyberbullying incidents only induces the aggressor to believe that he/she is right and powerful, and the victim will have a high risk of self-isolation, helplessness, depression, anxiety, and suicidal thoughts. In this sequence of changing roles, the importance of the teacher's intervention is crucial in reducing the incidence of aggressive behaviors.

The second explanation would be the focus on the didactic activity rather than the counseling activity - the teachers believe that the time should be invested in teaching, and the class time should be dedicated to science, for the benefit of all stu-

dents.

A third explanation can be related to the fact that some teachers consider fighting bullying at school useless because some of them are themselves victims of bullying by the same students who bully their colleagues.

Fourthly, the recognition of a problem must come together with the structuring of intentions to intervene over a long period, to find solutions together with students, parents, school management, school psychologists, and other stakeholders, which means that the teacher must invest time, effort, and resistance to stress, denial, and frustration from others.

Fifthly, the recognition of a behavior problem and some incidents that take place in the school space may induce the opinion that the other colleagues or the members of the school committee consider them unskilled in solving such cases, the explanation being, therefore, the desire to shield themselves from a negative evaluation from the teaching staff.

The sixth explanation could be due to the students' disclosure. A lot of studies show that students are not willing to report bullying incidents to their teachers, and most of them talk about an aggressive issue to a friend, a colleague, or a parent. Bullying incidents are deliberately hidden from teachers; in general, teachers' responses were perceived as ineffective, insensitive, or excessive, and even peers discourage 'telling tales' to adults. For example, some researchers (35-38) identified that pupils reported a reluctance to tell adults, particularly teachers, about their experiences of bullying, and this tendency increased with age. The implications of the present findings, also revealed by some scarce literature, are important for the advancement in anti-bullying policy and practice that received support from schoolteachers.

The seventh explanation is related to the personal aspects such as personality, life experience, familial-socio-professional status, and their own representation of bullying and cyberbullying and aggressive behavior in general. Some studies revealed that teachers with victimization antecedents were more prone to identify and interfere in cyberbullying incidents (32-25).

An eighth explanation could be related to the high level of knowledge about traditional bullying and a good package of skills applied in the classroom to stop bullying behaviors, a situation that makes teachers feel powerless in cyberbullying situations. For example, a study by Elledge *et al.* (39) and Paez (40) showed that when the students evaluated their teacher as highly capable of intervening in a traditional bullying incident, the other type of aggression-cyberbullying - increased. So, the perpetrators will try to find ways to aggress others by engaging in more covert instances of bullying (online) because traditional bullying incidents are more likely to be halted by their high-intervening teachers.

Taking into account the aspects mentioned above (which, of course, do not cover the entire range of explanations because they do not refer to others, such as cultural, religious, or ethnic variables as well as the legislative aspects specific to each country), the intervention and prevention programs that take place in schools, with the help of teachers, must be built in such a way that they are adapted to the needs of students but also to the possibilities of teaching staff to get involved in the management of bullying and cyberbullying incidents. (41-44) As we have sustained by the results of the present study, school

rules, peer-cultural acceptance of aggressive behaviors, the student-teacher relationship, but also the perception and previous experience of students regarding the ability of teachers to resolve aggressive incidents are important in the fight against cyberbullying. The involvement of teachers depending on the way in which they manage to overcome their own personal barriers in the face of repetitive aggressive behaviors should also not to be neglected.

Strengths and limitations of the study

The results of the present study are important because they mirror the current opinion of teachers regarding cyberbullying. Studies have shown an increasing use of the internet in the last decade. Apart from that, we must consider the enormous use of the internet and digital technologies in school activity, imposed by the COVID-19 pandemic lockdown all over the world. The research points out the big gap between the reality of cyberbullying and the lack of preparedness of teachers to deal with this impactful phenomenon.

This research has some limitations. The first limitation is related to the unbalanced gender distribution of respondents that is imposed by the specifics of the teaching profession. More women are embracing this job compared to men. The second limitation is due to the unbalanced distribution of respondents by country, and that is why comparative analysis must be treated with precociousness. But this limitation should also be seen as a productive one, because studies showed that cyberbullying is a widespread phenomenon, with no geographically related cause. The adverse effects caused by cyberbullying, including reduced safety, lower educational attainment, poorer mental health, and greater unhappiness among students in all countries, led UNICEF to state in 2017, that *"no child is absolutely safe in the digital world".* (45) The third limitation is determined by the restrictions imposed by the questionnaire. It did not consider variables that could influence teachers' opinions regarding cyberbullying, such as psychological troubles (depression, burnout), job-related factors (dissatisfaction with their job or with the relationships with students/colleagues/managers), the personal experience as a victim of cyberbullying or having a member in the family (husband, child) with such an experience, negative antecedents concerning solving cyberbullying problems among their students or being the victim of cyberbullying by one of the students in the school.

CONCLUSIONS

This research confirms the major role that teachers have in fighting the increasing phenomenon of cyberbullying and the fact that this role must be constantly prepared by awareness, training, and collaborative relationships with students, parents, and colleagues. The results are important for students, teachers, parents, and school staff in order to realize the tremendous need for good communication, for training and developing skills in order to manage cyberbullying by encouraging the disclosure of incidents, being able to identify cyberbullying in the school environment, and offering help to all those involved (victims, perpetrators and bystanders). The results showed that policy makers should consider teachers' experiences and needs in designing policies aimed at preventing and managing the online deviant behaviors among children and adolescence immediately that the aggressive acts are reported.

ACKNOWLEDGMENTS

This study is conducted within the project TECPC - Together Everyone Can Prevent Cyberbullying (2020-1-RO01-KA226-SCH-095269), in the framework of the ERASMUS+ Programme -KA2 Strategic Partnerships Digital Education Readiness.

THE SIGNIFICANCES OF LYFESTYLE, ASSOCIATED DISEASES AND ANATOMICAL VARIANTS OF CIRCLE OF WILLIS IN THE FORMATION OF ANTERIOR COMMUNICATING ARTERY ANEURYSMS (Abstract): Intracranial aneurysm represent a cerebrovascular disease with a relatively low incidence, but among these the most common are aneurysms developed in the anterior part of the circle of Willis (CoW). **Material and methods:** We collected the demographic and morphological data of the patients admitted in "Prof. Dr. N. Oblu" Emergency Clinical Hospital, Iași, Romania, with ruptured AcomA aneurysms, who later deceased and were autopsied in the Pathology Department of the same hospital, over a period of 6 years (January 2014 to December 2019), and analyzed data related to: age, gender, lifestyle (heavy smoking and alcoholism), type of anatomical variant of circle of Willis, and presence of any associated diseases. **Results:** We identified 7 patients with ruptured AComA aneurysm. 57.14% were male patients. The average age was 60.85 (range 34 to 69). Left posterior communicating artery (PcomA) was hypoplastic in 100% of all deceased patients. Right PComA presented hypoplasia (71.42%) or fetal type variant (28.57%). 71.42% of all cases showed anatomical variants both in the anterior and the posterior part of CoW. 66% of the female patients with AComA aneurysm presented obesity, type 2 diabetes, atherosclerotic disease and hypertension. 100% of male patients presented hypertension and atherosclerotic disease, 75% of them were chronic alcohol consumers and 50% were heavy smokers. **Conclusions:** The lifestyle, associated diseases, and anatomical variants of the component arteries of the circle of Willis, both from its anterior and posterior parts, could be risk factors for the formation of anterior communicating artery aneurysm. **Keywords:** CIRCLE OF WILLIS, ANTERIOR COMMUNICATING ARTERY ANEURYSM, ANATOMICAL VARIANTS, LIFESTYLE.

Intracranial aneurysm represents a cerebrovascular disease with a relatively low incidence, as it ranges between 3.6 - 9% in the general population (1, 2).

Aneurysms located at the circle of Willis (CoW) level are defined as a localized dilatation of a component artery, being situated at weak points along this anatomical structure. Approximately 85% of aneurysms develop in the anterior part of CoW, predominately at its bifurcations (3). Aneurysms of anterior communicating artery (AComA) are the most common, representing 23% - 43.5% of all intracranial aneurysms (4-6).

Over time, numerous theories have emerged about the development of an intracranial aneurysm. At first it was considered that the embolic and inflammatory reactions were the significant factors in this process, but later it was found that the presence of some defects in the development of the vascular media at the bifurcation of an artery are necessary. In addition, some degenerative changes of muscle of the vascular media, as well as of internal elastic membrane were associated (7).

More recently, Stojanović *et al.* (2) concluded that the asymmetric configuration of the circle of Willis causes increased perfusion requirements in certain areas and thus initiates the process of blood vessel remodeling in the area of permanently increased perfusion flow. Some of the risk factors that contribute to the occurrence of an intracranial aneurysm have been identified so far: familial history of intracranial aneurysm, high blood pressure, cigarette smoking, alcohol consumption, and female gender (8). However, these factors do not seem to explain the entire way of aneurysm formation, especially in the case of AComA, because in 1991 some Japanese researchers published an article about an AComA aneurysm diagnosed in a 13-month-old child (9).

During its evolution, the AComA aneurysm ruptures and leads to the occurrence of subarachnoid hemorrhage, often with ventricular involvement, leading in 30-40% of cases to death or severe neurologic dysfunction and disability in survivors (8).

The hypothesis that anatomical variants of the component arteries of CoW can influence the formation of intracranial aneurysms was first reported by Padget *et al.* in 1944 (10). Considering AComA aneurysms, hypoplasia of one or both Anterior Cerebral Arteries (ACAs) play a defining role in its development by disturbing local hemodynamics (11-14). There are only few studies identifying the presence of a fetal-type of Posterior Communicating Artery (PComA) in patients with AComA aneurysms (15-17).

The first aim of our study was to analyze the anatomical variants of the anterior and posterior parts of CoW in a series of autopsy specimens in order to identify the relationship between any of its component arteries and AcomA aneurysm formation and rupture. Our second aim was to identify the risk factors that intervene in the formation and rupture of an AComA aneurysm by analyzing associated diseases and lifestyle of the patients included in our series.

MATERIAL AND METHODS

We collected the demographic and morphological data of the patients admitted in the main neurological and neurosurgical regional centre in North-Eastern Romania ("Prof. Dr. N. Oblu" Emergency Clinical Hospital of Iasi) with ruptured AComA aneurysms, who later deceased and were autopsied in the Pathology Department of the same hospital, over a period of 6 years (January 2014 to December 2019), analyzing both medical records and protocols of the autopsies.

Based on the resulting list, we created a database with the following data:

1. Demographic data: age, sex, lifestyle (heavy smoking and alcoholism)

2. Morphological data: the presence of any type of anatomical variant for each component artery of CoW, taking into account the literature definitions, as well as the presence of any associated diseases (obesity, hypertension, type 2 diabetes).

According to literature, we considered that:

- "hypoplasia" of a component artery of CoW is defined by an external diameter of less than 1 mm, except for communicating arteries, which are considered hypoplastic at an external diameter of less than 0.5 mm (18).
- the posterior communicating artery (PComA) is defined as complete fetal (fPComP) when it originates entirely from the internal carotid artery (ICA), with no connection to the Basilar Artery (BA). We defined the posterior communicating artery as partially fetal (pfPComA) when it originates from ICA and retains a small atresic connection with BA (19).

The obtained results were collected in a database using the *Microsoft Excel* 2007 program and were used to calculate the mean, number and percentage, as well as to make the corresponding graphs. At the end, we compared our results with the data from the specialized literature.

RESULTS

We identified 7 deceased patients with ruptured AComA aneurysm and fatal outcome. Among them, 57.14% were male patients (fig. 1), with a M:F ratio of 1.33. The average age of the patients from our series was 60.85 (range 34 to 69). Mean age of female patient was 66 (range 60 to 69), while for male patients was 57 (range 34 to 71).

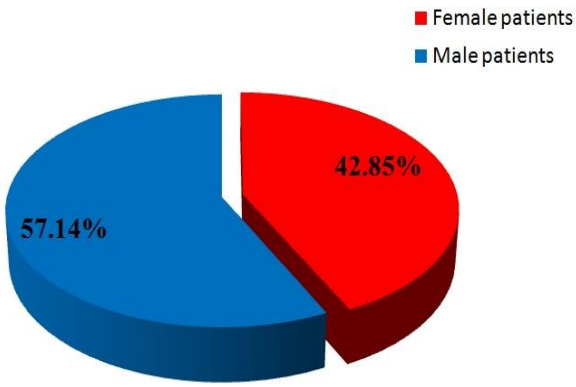

Fig. 1. Chart showing the gender ratio

Macroscopic examination showed that none of our patients presented a symmetrical circle of Willis. AComA presented a normal conformation in 100% of all cases but left PComA was hypoplastic in 100% of all deceased patients. Right PComA presented hypoplasia in 71.42% of cases and partial fetal type in 28.57% of cases.

All other vessels presented only hypoplasia. Right ACA presented hypoplasia in 57.14% of all cases, but left ACA showed hypoplasia only in 14.28% of the analyzed specimens. Right Posterior Cerebral Artery (PCA) was hypoplastic în 28.57% of the deceased patients and left PCA in 14.28% of cases (fig. 2).

57.14% of all circles of Willis presented three anatomical variants, 28.57% had four variants, and 14.28% exhibited only two variants (fig. 3).

In our series, 71.42% of all cases presented anatomical variants both in the anterior and the posterior part of CoW. 28.57% presented variants only in the anterior part. None of the analyzed cases had only the anterior part affected (0%) (fig. 4).

The analyzed AComA aneurysms varied in diameter from 4 mm to 13 mm, with a mean diameter of 8.42 mm (figs. 5-7).

66% of the female patients who died with AComA aneurysm were previously diagnosed with obesity, type 2 diabetes, atherosclerotic disease and arterial hypertension, but none were heavy smoker or alcohol drinker. 100% of male patients with AComA aneurysm were previously diagnosed with arterial hypertension and atherosclerotic disease, and 75% of them were chronic alcohol consumers and 50% were heavy smokers (fig. 8).

Fig. 6. M, 50 years old. AComA ruptured aneurysm (white arrow), with a diameter of 4mm) with subarachnoid hemorrhage associated with left ACA hypoplasia (blue arrow), right PComA hypoplasia (yellow arrow), partial fetal type left PcomA (green arrow), and left PCA hypoplasia (purple arrow).

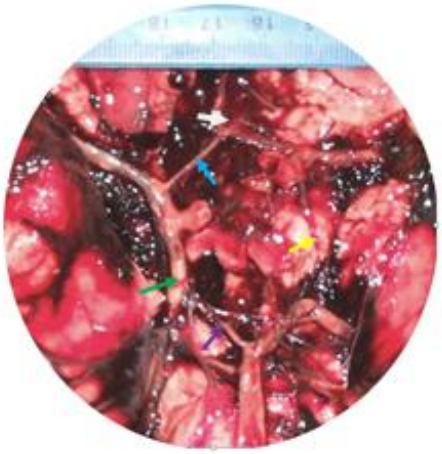

Fig. 7. F, 60 years old. AComA ruptured aneurysm (white arrow), with a diameter of 8mm, with subarachnoid hemorrhage and massive intraventricular hemorrhage associated with right ACA hypoplasia (blue arrow), partial fetal-type right PcomA (green arrow), right PCA hypoplasia (purple arrow), and left PComA hypoplasia (yellow arrow).

DISCUSSION

Regarding the circle of Willis, aneurysms developed mostly in the anterior part (20, 21). Literature unequivocally states that ruptured intracranial aneurysms are associated with the female sex (8), but, in the case of AComA aneurysms, male patients outnumbered female patients (22, 23). Ghods *et al.* also found that male patients with ruptured AComA aneurysm were diagnosed at a significantly younger age than female patients (23). Even though our series included a small number of cases, we identified the same gender differences and found out that male patients were diagnosed with ruptured AComA aneurysms 9 years earlier than female patients.

Previous angiographic studies demonstrated that abnormalities of the AComA complex, most frequently hypoplasia of A1 segment of ACA, are associated with AComA aneurysm in more than two thirds of cases (11, 12, 24, 25). Our study demonstrated on an autopsy series the same association in almost three quarters of the cases.

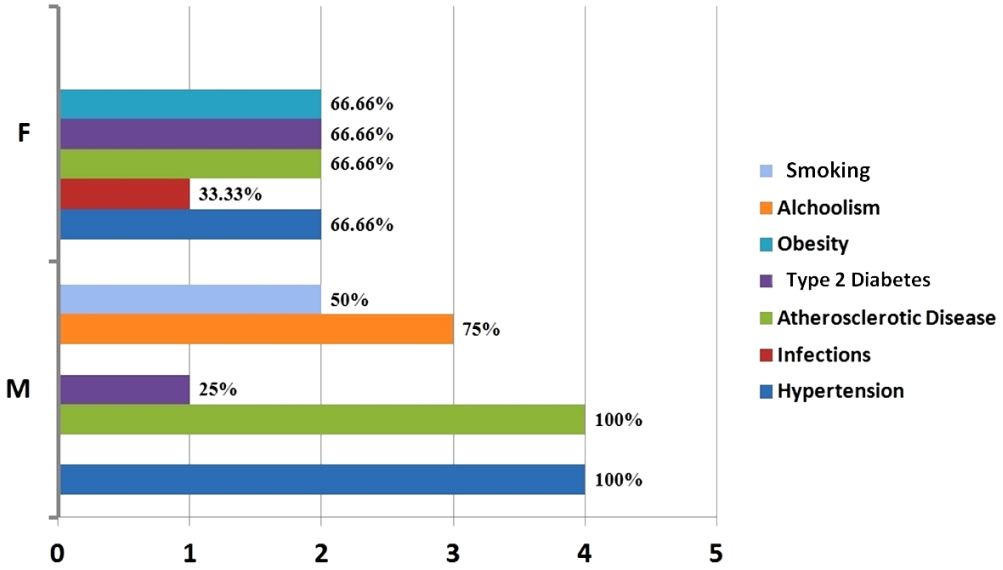

Fig. 8. Chart showing the relation between gender and associated diseases to the AComA aneurysm. Abbreviations: M=male patients; F=female patients

Tarulli and Fox, in 2010, showed that the presence of an asymmetric configuration of the A1 segment of ACA facilitates the development of AComA aneurysms by flow stresses (13). More recently, in 2017, Rinaldo *et al.* analyzed digital subtraction angiography images of 204 patients with AComA aneurysm. Of their patients, only 1/6 were found to have a hypoplastic A1 segment, even if they had no history of smoking (14), but they also took into consideration the unruptured aneurysms.

The relative lack of traditional risk factors for aneurysm formation (such as smoking) in patients with A1 segment hypoplasia should direct researchers' attention to investigating some other hemodynamic factors with a role in AComA aneurysm

formation. Therefore, it may be of interest to search for associations between AComA aneurysm and some other types of anatomical variants along with A1 segment hypoplasia. We already found in our series that patients with AComA aneurysm presented an association between hypoplasia of A1 segment and hypoplasia or partial fetal type of at least one of the two PComAs.

Rinaldo *et al.* reported that AComA aneurysms associated with hypoplastic A1 segment have a mean diameter of 7.7 mm (14), a value similar to that identified in our study.

A group of Turkish researchers analyzed the intraoperative anatomic vascular variations associated with AComA aneurysms in 120 patients. They found that more than half of them had anatomical variants in the vicinity of the AComA aneurysm, such as: marked hypoplasia of the A1 segment in more than a quarter of cases, but less often the median artery of the corpus callosum, duplication of AComA, duplication of A1 segment and azygos artery (26). Another intraoperative study conducted on 130 cases with AComA aneurysms by Bazowski *et al.* identified anatomical variants in more than one third of them. The most common abnormality reported was hypoplasia of the A1 segment of ACA (27). More than one third of Polish patients and one-third of Egyptian patients with AComA aneurysms were reported to present hypoplasia/aplasia of A1 segment of ACA (28-30). Thus, aneurysms of AComA were most often associated with an asymmetry of A1 segment of ACAs.

As far as we know, only recently were published three articles that angiographically confirmed the role of partial fetal type AComP associated with hypoplasia of A1 segment of ACA in the formation and rupture of the AComA aneurysm as a result of hemodynamic stress in susceptible patients (16-17). So, our article brings more knowledge to this matter.

The hypothesis that anomalies of the posterior part of CoW could play a role in the development of AComA aneurysm seems to be possible because in cases with hypoplasia of PCA, the blood from the ICA is no longer directed to the ipsilateral PCA and thus the blood pressure is directed to the ipsilateral ACA and implicitly to the AComA, favoring the development of aneurysms at this location by increasing the flow pressure, even in the absence of an anatomical variant of any of the two ACAs.

Considering the formation of aneurysms along CoW, Permiakov *et al.* emphasized the fact that the etiopathogenetic element underlying the appearance of such an aneurysm is the existence of congenital dysplasia of the arterial wall, which is also associated with certain risk factors such as essential or transient arterial hypertension and atherosclerosis (21). Other authors have considered the following as risk factors for the occurrence of intracranial aneurysms: smoking, hypertension, excessive alcohol consumption, one or more relatives affected with subarachnoid hemorrhage, autosomal dominant polycystic kidney disease, and a previous episode of subarachnoid hemorrhage (31).

Recent evidence shows that type 2 diabetes and atherosclerosis share common mechanisms for arterial wall alteration, such as lipid regulation, apoptosis, endothelial activation and inflammation, mitochondrial oxidative stress, changes in extracellular matrix components, and disruption of cellular defense systems (32).

On the other hand, in arterial hypertension all layers of the vascular wall are af-

fected due to aberrant vascular signaling, oxidative and inflammatory responses. Subsequently, hypertensive vasculopathy predisposes to atherosclerosis as a result of increased transmural pressure, blood flow and shear stress, as well as endothelial dysfunction and vascular stiffness (33). On the other hand, obesity directly contributes to cardiovascular risk factors, being itself associated with obvious atherosclerotic lesions (34). Therefore, it seems reasonable to state that the presence of hypertension, type 2 diabetes and obesity may be risk factors for the occurrence of AComA aneurysm as we found in our series.

Literature reveals that smoking plays a role both in aneurysm formation, its growth, its rupture, as well as in its recurrence after endovascular repair, probably due to the effects that the cigarette substances have on the artery walls during a multi-step process, i.e. initial vascular inflammation and hemodynamic stress, then endothelial dysfunction, and, finally, wall weakening and rupture (35, 36).

CONCLUSIONS

Our study brings new information regarding the association between patients' gender and certain risk factors for the formation, progression, and rupture of Anterior Communicating Artery aneurysm. We can conclude that the lifestyle (alcohol consumption, and heavy smoking) of our patients as well as their associated diseases (obesity, type 2 diabetes, atherosclerotic disease, arterial hypertension) could represent risk factors in the formation and rupture of Anterior Communicating Artery aneurysm. Also, the hemodynamic factor must also be taken into consideration because all our patients with Anterior Communicating Artery aneurysm presented at least two anatomical variants of the component arteries of the circle of Willis, both from its anterior and posterior parts. We emphasize the fact that neuroradiologists and neurosurgeons must keep in mind that, in cases with an unruptured Anterior Communicating Artery aneurysm, not only the anatomical variants of Anterior Cerebral Arteries should be searched on computed tomography angiographies or Magnetic Resonance Angiography, but also the anomalies of the posterior part of the circle of Willis in order to prevent the rupture of that aneurysm.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest regarding this scientific research. This article was co-funded from the European Social Fund - the Human Capital Operational Programme, Project/ Grant No: POCU/993/6/13/154722.

ETHICAL APPROVAL

The current study was approved by the Ethics Committee of "Prof. Dr. N. Oblu" Emergency Clinical Hospital Iasi, Romania.

RENAL FUNCTION DYNAMICS IN PATIENTS WITH RADICAL PROSTATECTOMY FOR PROSTATIC ADENOCARCINOMA (Abstract): Renal function parameters, readily assessed through routine blood tests, have been largely unexplored in relation to prostate cancer. This study aims to investigate the associations between renal function parameters (creatinine, urea, estimated glomerular filtration rate-eGFR), both pre- and post-prostatectomy, and histopathological characteristics of prostate adenocarcinomas. Additionally, it evaluates potential correlations with prostate biochemical recurrence, offering insights into kidney function dynamics post-prostatectomy. **Material and methods:** We analyzed data from 72 patients with prostate adenocarcinoma who underwent radical prostatectomy. Histopathological reevaluation was conducted, including Gleason score, pT stage, prognostic grade groups, and biochemical recurrence assessment. Preoperative and postoperative renal parameters were recorded, and eGFR was calculated using the CKD-EPI formula. Statistical analysis was performed to assess associations. **Results:** Preoperative eGFR showed a significant association with Gleason score and prognostic grade groups ($p<0.05$). However, there were no significant correlations between renal parameters and biochemical recurrence or pT stage. **Conclusions:** This study emphasizes the potential utility of eGFR as a marker for identifying prostate adenocarcinomas with higher Gleason scores and prognostic grade groups. While the complexity of renal function dynamics in prostate cancer warrants further investigation, our findings contribute to understanding the intricate relationship between kidney function and prostate tumor behavior. **Keywords:** RENAL FUNCTION, PROSTATE CANCER, CREATININE, UREA, eGFR.

Prostate cancer (PCa) is the most commonly diagnosed urologic male malignancy worldwide (1), with more than 1.4 million new cases in 2020 and a global mortality rate of 7.7/100,000 (2). From a histopathological perspective, conventional acinar adenocarcinomas (ADKs) and their less common histological variations,

account for over 95% of prostate cancers, while less prevalent types include non-acinar carcinomas, such as sarcomas and neuroendocrine tumors (3).

Prostate-specific antigen (PSA) remains the predominant biomarker used in prostate cancer screening (4) and also plays a crucial role in treatment strategy selection and predicting biochemical recurrence (5, 6).

While histopathological characteristics for prostate cancer continue to be refined and augmented by innovative molecular classifications (7), the quest for novel biochemical parameters that can provide insights into the broader systemic and organ-level implications of this neoplasia remains ongoing. In the context of increasing longevity among the population, there is a noticeable overlapping between conditions such as chronic kidney disease and PCa (8). Parameters related to renal function, which are readily assessable through routine blood tests, may be influenced by neoplastic conditions. However, there is a paucity of research examining the importance of these parameters in prostate cancer and their potential associations with the histopathological features of this malignancy (9, 10).

Therefore, the aim of our study is to investigate the relationships between renal function parameters (creatinine, urea, estimated glomerular filtration rate), both pre- and post- prostatectomy, and the histopathological characteristics of prostate adenocarcinomas. Furthermore, it is the first study to evaluate the possible associations between these nephrological parameters and prostate biochemical recurrence, hence assessing their potential prognostic significance. These potential correlations may help identify new insights into the complex dynamics of kidney function in patients who have undergone prostatectomy for prostate cancer. The analysis of renal function could be integrated as a potential indicator of aggressiveness level of prostate acinar adenocarcinoma, facilitating patient stratification.

MATERIAL AND METHODS

Patients, histopathological assessment and nephrological parameters

The study cohort comprised 72 patients diagnosed with prostate adenocarcinoma and who underwent radical prostatectomy at the "Dr. C. I. Parhon" University Hospital in Iaşi, Romania, between 2010 and 2018. This research obtained ethical approval from the Research Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy, Iaşi, (No. 292/2023).

Each case underwent a microscopic reevaluation following the guidelines provided in the most recent edition of the World Health Organization (WHO) classification for tumors of the urinary and male genital systems, released in 2022 (11). During this reevaluation, we reassessed various aspects, including the Gleason score, the dominant pattern, and aggressiveness parameters such as capsular, perineural, and lymphovascular invasion, as well as the pathological tumor-node-metastasis (pT) stage, and subsequently attributed prognostic grade groups.

Biochemical recurrence was defined as serum PSA values $\geq$ 0.2 ng/mL following radical prostatectomy.

Preoperative and postoperative paraclinical biochemical parameters (postoperative PSA levels, serum creatinine and serum urea) were recorded from the patients' medical charts.

Using the 2021 calculation formula from the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) (12), we computed estimated preoperative and postoperative glomerular filtration rates by taking into account serum creatinine levels and age.

For each renal function-associated parameter we evaluated the distribution in our study lot and calculated a cutoff value based on the median, used for grouping the cases in order to apply the statistical Chi-square test for assessing the relation to other parameters.

Statistical analysis

Associations between the histopathological features (Gleason score, pT stage, prognostic grade groups and biochemical recurrence) and the preoperative and post operative renal parameters (serum creatinine, serum urea and eGFR) were evaluated using Chi-square test at the critical significance level p=0.05.

Statistical analysis was conducted using *Statistica version 7* (Tibco, Palo Alto, CA, USA) and *Excel 2016 version 16.0* (Microsoft, Redmond, WA, USA).

RESULTS

Pathological features of the study lot

The defining histopathological characteristics of each case in our study lot, reconsidered in accordance with the updated 2022 WHO Classification for tumors of the urinary and male genital systems (11), are detailed below (tab. I).

TABLE I.

General histopathological characteristics of the study lot

Case no.	histological variant / associated variant	Gleason Score	pT	Prognostic grade group	Biochemical recurrence	Invasion		
						Cp	Pn	Lv
1	conv. acinar/mucinous	6=3+3	T1	1	present	present	present	absent

72	conv. acinar	7=3+4	T3	2	absent	present	present	absent

Conv=conventional, Cp=capsular, Pn=perineural, Lv=lymphovascular.

All reevaluated cases were conventional acinar adenocarcinomas, with certain cases showing associated histopathological variants: foamy cell (12.5%), mucinous (6.94%), atrophic (0.72%) and microcystic (0.72%). The predominant Gleason score was 6 (52.77% of cases) and the main Gleason pattern was 3 (76.38% of cases). The majority of cases presented neoplasic involvement of the prostate capsule (99.66%), with perineural spread of the tumor (84.72%). Lymphovascular invasion was observed in only 20.83% of cases. In 19 cases (26.38%), the tumor had extended beyond the confines of the prostate, resulting in a pT3 stage and biochemical recurrence was confirmed in 48.61% of cases.

Renal function parameters

The identified values for preoperative and postoperative serum creatine, serum urea and eGFR led to the median levels comprised in the table below (tab. II).

TABLE II.

Preoperative and postoperative values of renal function parameters

Renal function parameter	Range	Median Value
Preoperative Creatinine (mg/dL)	0.6-2.2	0.885
Preoperative Urea (mg/dL)	11-62	30
Preoperative eGFR (mL/min/1.73m^2)	33-111	94
Postoperative Creatinine (mg/dL)	0.67-1.7	0.9
Postoperative Urea (mg/dL)	17-66	33
Postoperative eGFR (mL/min/1.73m^2)	44-110	95

Correlations between renal function parameters and histopathological features

There were no statistically significant correlations between the biochemical recurrence and the preoperative and postoperative renal parameters. Also, there were no significant associations between pT stage and renal parameters, both preoperative and postoperative.

The only notable and statistically significant association was registered between the preoperative eGFR and the Gleason score and prognostic grade groups, respectively (tab. III).

TABLE III.

Correlations of renal function parameters and histopathological features of PCa

Renal function parameter	Biochemical recurrence			Gleason score			Prognostic grade group			pT stage		
	P	A	p	≤7	>7	p	1-2	3-4	p	1-2	3-4	p
preoperative creatinine (< 0.88 mg/dL)	16	16	0.832	26	6	0.671	22	10	0.172	24	8	0.810
preoperative creatinine (≥ 0.88 mg/dL)	19	21		34	6		33	7		29	11	
preoperative urea (<30 mg/dL)	18	15	0.354	28	5	0.750	25	8	0.907	24	9	0.875
preoperative urea (≥30 mg/dL)	17	22		32	7		30	9		29	10	
preoperative eGFR (< 94)	16	18	0.803	32	2	0.02	21	3	0.03	28	6	0.111

Renal function parameter	Biochemical recurrence			Gleason score			Prognostic grade group			pT stage		
	P	A	p	≤7	>7	p	1-2	3-4	p	1-2	3-4	p
preoperative eGFR (≥ 94)	19	19		28	10		24	14		25	13	
postoperative creatinine (< 0.9 mg/dL)	15	20	0.342	30	5	0.598	26	9	0.682	27	8	0.505
postoperative creatinine (≥ 0.9 mg/dL)	20	17		30	7		29	8		26	11	
postoperative urea (< 33 mg/dL)	17	18	0.994	29	6	0.916	26	9	0.682	27	9	0.899
postoperative urea (≥ 33 mg/dL)	18	19		31	6		29	8		26	10	
postoperative eGFR (< 95)	19	15	0.242	27	7	0.398	26	9	0.682	22	12	0.104
postoperative eGFR (≥ 95)	16	22		33	5		29	8		31	7	

There were no significant correlations between the aggressiveness indicators (capsular, perineural and lymphovascular invasion) and renal function parameters, both preoperative and postoperative (p value 0.05 for t-test).

DISCUSSION

In the context of evaluating the overall health of individuals with prostate adenocarcinomas, the assessment of kidney functionality is an integral aspect of their perioperative management, with a crucial role especially in anti-androgen therapy (13). Several studies have been conducted in this direction, demonstrating that renal dysfunction can occur as early as one month after the institution of hormone deprivation therapy, persisting throughout the duration of treatment (14). This dysfunction can be attributed to various mechanisms, such as hyperglycemia and dyslipidemia, which can disrupt glomerular function by affecting interstitial tubule membranes. Additionally, hormone castration leads to testosterone depletion, which can counteract the vasodilatory effects of testosterone on renal blood vessels. Furthermore, this hormonal imbalance can result in estrogen deficiency, which has negative implications for renal tubular function (15).

Although these studies collectively highlight the complex relationship between hormone therapy, renal dysfunction, and the underlying physiological mechanisms involved, there is limited data on assessing renal function indicators with actual clinical or histopathological parameters of prostatic carcinoma. Only two recent studies focused on the relationship between total PSA levels and uric acid levels (16), and several renal parameters (creatinine, urea, uric acid and cystatin C) respectively (17).

In light of this data, our study stands out as the first effort to assess how various kidney function indicators (including creatinine, urea and eGFR), both pre- and post- radical prostatectomy, relate to the histopathological parameters that define the clinical behavior of prostatic adeno-carcinomas, ultimately influencing treatment outcomes and responses. Our results revealing a statistically significant correlation between preoperative eGFR and

Gleason score, and consequently with the prognostic groups. These findings are concordant with a recent study, supporting, through a multivariable analysis, after controlling for age, BMI, prostate-specific antigen doubling time (PSA), Gleason score, and clinical stage, the role of a statistically significant predictor of overall mortality after radical prostatectomy (18).

Surprisingly, we did not observe any noteworthy correlations between serum creatinine and urea levels and the histopathological characteristics of prostate adenocarcinomas, including capsular, perineural, and lymphovascular involvement. One potential explanation for these findings may be linked to the relatively small size of our study lot. Additionally, it's important to note that the majority of cases in our study comprised localized prostate adenocarcinomas limited to the prostate gland, thus lacking aggressive characteristics related to extensive tumor spread, which could contribute to the absence of significant associations with kidney function indicators.

CONCLUSIONS

While the underlying pathogenetic mechanisms of renal damage in prostatic neoplasia remain incompletely understood, our study has shed light on the potential role of eGFR as a valuable marker for identifying prostate adenocarcinomas associated with higher Gleason scores and prognostic grade groups. This finding opens up perspectives for a more comprehensive understanding of kidney function dynamics in the context of prostatic malignancy.

THERAPEUTIC OBSTINACY AT THE END OF LIFE - CREATING A TOOL FOR RESEARCHING THE PERCEPTION OF HEALTHCARE PROFESSIONALS (Abstract): Introduction: The delivery of end-of-life care presents ethical quandaries regarding the delineation between therapeutic efficacy and the potentially ambiguous advantages of subjecting individuals with terminal illnesses to medical interventions. Therapeutic obstinacy at the end of life represents medical interventions that are inappropriate for the patient's clinical condition and circumstances, considering their potential outcomes, expectations, and burdens on the patient and family. These procedures try to prolong life rather than help it progress naturally. End-of-life care workers often have different views on therapeutic obstinacy and futile therapies, which affects their overall view of this type of care. The **aim** of this study is to create a questionnaire to collect data on health care professionals' perceptions of therapeutic obstinacy at the end of life. **Materials and methods**: To fulfill the objective of this work, a qualitative investigation was conducted, comprising the formation of three focus groups and the implementation of two pilot surveys. The aforementioned steps were taken to ensure that the questionnaire devised would effectively address the research objectives by acquiring information that is valid, accurate, and dependable. **Results:** The questionnaire created collects data on the perception of health care staff about interventions considered to be excessive and futile at the end of life, about the causes and pressure factors in these situations, as well as possible solutions to reduce this phenomenon. **Conclusions:** The perspectives obtained from the survey conducted in this study hold potential significance for professionals working in the fields of palliative care, oncology, critical care in ICU, emergency medicine, as well as individuals aspiring to pursue training and careers in these domains. Furthermore, the findings derived from our comprehensive study will serve as a significant contribution to the current discourse on ethical considerations within the realm of end-of-life care. **Keywords:** THERAPEUTIC OBSTINACY, FUTILE TREATMENT, END OF LIFE, HEALTH-CARE PROFESSIONALS.

Death is a natural, inevitable part of life. However, death is often treated as a disease (1) and people's attitudes to it vary according to culture, religion, tradition or personal

conscience (2. Individual perspectives on death can influence attitudes in end-of-life care and are essential given that one of the most important principles of good medical care is conforming to the patient's wishes and values (1-4). Medicine has always tried to go beyond the limits of life, often through technological and scientific progress. For example, modern intensive care techniques now make it possible to keep alive patients with pathologies that were considered lethal in the past by compensating for organ failure (2). In the latter part of the 20th century, advances in biomedical technology have led us to consider a "good death" as one involving disease control. Partly in response to this view, the modern palliative care movement has emerged, redefining a "good death" as one that includes acceptance of the end of life (5).

Medical practice and the approach to the end of life have changed drastically due to constant scientific and technological development (6). Thus, health professionals are faced with situations that promote not only life-prolonging care but also a culture of death denial, which can create significant difficulties in determining the prognosis of critically ill patients (7) and complex ethical concerns such as the utility of known therapies and treatments (8). From the perspective of patient demand and supply in the health care business, moral hazard makes mortality expensive (9-11). The last weeks of life receive a disproportionate share of healthcare expenditures, promoting inequity (12-13). To live to the end is the "right to die with dignity"- not to die. Medical practitioners and society need to comply with dying ethics (14). Palliative care addresses these ethical standards. Thus, most believe that artificially prolonged anguish degrades the death (4, 14).

Palliative care relieves suffering, improves QoL, and lowers healthcare costs for persons with significant chronic illnesses and their families from diagnosis through death (15-16, 17-18). It is a type of care provided by trained clinicians (specialist palliative care, - SPC) and/or by primary care, community, or hospital employees with basic palliative care training (19).

Defining the end of life

End of life is the final common pathway of many progressive diseases with irreversible decline of the body's functional state before death (20). In the literature, there are different assessments of the length of time that characterize the concept of the end of life. Certain research pertaining to end-of-life care focuses on the final stages of an individual's life, namely the concluding days, hours, or minutes (21). One of the most common definitions of the end of life is that developed by the National Hospice and Palliative Care Organization (NHPCO), which specifies the temporal nature of a period of less than six months of expected life. NHPCO states that end-of-life care or hospice care begins when a person has a diagnosis of terminal illness with less than six months to live and curative treatments have been exhausted. (20-21).

Therapeutic obstinacy and therapeutic futility

End-of-life care, since its early history, has been recognized as raising significant ethical concerns for medicine (22). Interventions such as cardiopulmonary resuscitation, mechanical ventilation, mechanical circulatory support, artificial nutrition and hydration, terminal sedation, non-initiation

and discontinuation of treatment, euthanasia, and physician-assisted suicide are issues that correspond to circumstances in which end-of-life decision-making difficulties ap-pear to be of greatest importance (23-25).

According to the *Pallipedia Medical Dictionary*, therapeutic obstinacy is "the initiation or continuation of medical actions that have no other aim but to prolong the patient's life when the patient is facing irreversible death" (26). Therapeutic obstinacy describes medical interventions that only delay death and do not allow life to unfold, which are inappropriate to the patient's clinical reality and situation in relation to the results, hopes, and burden they cause to the patient and family. It is an overzealous, unjustifiable therapeutic urge that pro-longs death without benefiting the patient, causing artificial anguish (27). It creates the illusion of a long life for patients who have no chance of a cure or of minimally preserving quality of life, thus becoming a useless and upsetting treatment (28).

The dividing line between therapeutic obstinacy and timely therapy is one of ethical and clinical reasoning, which considers the complex reality of the advanced and/or terminally ill patient. The criteria that characterize therapeutic obstinacy in end-of-life care relate to the ineffectiveness of care interventions, the pain or burden on the patient, and the exceptionality of the interventions proposed. Proportionality or disproportionality of care are judgements that derive from the relationship between the therapeutic means used and the clinical reality of the patient to whom it is applied. When the clinical situation requires it, it is more useful for the patient to intervene through palliative care than by insisting on treatments with illusory curative aims (27-28). The "prognostic" factor is therefore important in assessing the appropriateness of certain medical interventions at the end of life in relation to the benefits obtained (29). In clinical practice, however, it is very difficult to decide what therapeutic obstinacy truly is, requiring great professional competence, clinical experience, a sense of proportion, as well as the continuous updating of therapeutic guidelines and the ongoing progress of clinical research in the field (24).

Personalist bioethics assesses end-of-life interventions as therapeutic obstinacy, the use of futile therapies that increase patient suffering and are dis-proportionate to the risk-benefit binomial, actually prolonging the dying process without providing healing or increasing the patient's quality of life; they are characterized by futility, suffering caused, and disproportionality. Disproportionality is judged by the patient, the physician, the patient's family, society, and the Bioethics Committee of the medical institution where the patient is ad-mitted (30).

Although therapeutic obstinacy and futile therapies are concepts with different meanings, they are often considered synonymous. Thus, according to some authors, "therapeutic futility" can be defined as treatments that do not provide immediate or long-term benefit to the patient (31). A medical procedure/treatment is considered "futile" when it meets one or more of the following five criteria: 1) the burden outweighs the benefits; 2) the patient has no chance of survival outside the intensive care unit; 3) the patient is in an irreversible coma; 4) the procedure does not meet the patient's expectations; and 5) death is imminent (32). Despite years of debate, futile therapy can delay or pro-long death (33)

and create moral distress for patients, families, and healthcare providers (34). For healthcare professionals, it can be a difficult ethical dilemma-ma to decide when to stop or not initiate futile treatments. Conflicts can arise when physicians and patients have different perspectives on treatment goals. Tensions can also arise when patients or their families request futile therapies (31-34).

In our opinion, the distinction between "therapeutic futility" and "therapeutic obstinacy" is related to questions about the third element of human action, i.e. circumstances. We consider that some therapies may be futile at the end of life (e.g. vitamin therapy for prophylactic purposes), (35) but they do not also fulfil the condition of disproportionality and prolongation of the dying process. In this context, we consider that "therapeutic obstinacy" is the most appropriate term for this concept. According to the results of a literature review published in 2016 (36), therapeutic futility in the Intensive Care Unit (ICU) can have a negative impact on professional satisfaction and induce emotional exhaustion in ICU physicians and nurses, with related consequences for patients and their families (37).

The aim of our study is to create a research tool to investigate the views of health care professionals on therapeutic futility in end-of-life care. The questionnaire is designed to collect data on the opinions of healthcare professionals about end-of-life care interventions, which they rate as disproportionate in relation with the benefits, about the causes of therapeutic obstinacy and pressure factors in such situations, and about the solutions to reduce therapeutic obstinacy in end-of-life care. No instrument has been identified in the Romanian literature that explores the perception of health care professionals regarding therapeutic obstinacy at the end of life. It is interesting to collect data on the opinion of medical staff about interventions considered disproportionate and futile at the end of life, the causes and pressure factors in these situations, and possible solutions to reduce this phenomenon. Such data are of interest to palliative care, oncology, and critical care practitioners in ICU and emergency medicine, to those who intend to train and practice in these fields, and will provide input to debates on ethical issues in end-of-life care.

MATERIALS AND METHODS

In order to achieve the proposed aim, qualitative research was carried out, which included three focus groups and two pretests (pilot surveys), so that the questionnaire would allow valid, accurate, and reliable data to be obtained. The starting point in developing the questionnaire was a literature review that high-lighted a concern for research on ethical issues related to good practice in end-of-life care, namely therapeutic obstinacy and futile treatment at the end of life.

The participants in the first two focus groups and the two pilot surveys were nurses with experience in end-of-life care: surgery, ICU, oncology, radiotherapy, and palliative care departments in two hospitals, one public-the Regional Institute of Oncology of Iași and the Palliative Care Hospital in Vaslui. The participants of the third focus group were physicians from different specialties in the above-mentioned hospitals and medical scholars caring for patients at the end of life: ICU, radiotherapy, oncology, surgery, palliative care, and forensic/bioethics.

The data from the literature were cor-

roborated with the suggestions of the participants in the three focus groups and the two pretests, resulting in the final version of the research questionnaire. All three focus groups were conducted face-to-face, audio recorded, and later transcribed verbatim. This was followed by the management, organization, and thematic analysis of the data, followed by the rereading of the texts, the thematic separation of the data, the identification of themes and sub-themes, and coding. The questions in the questionnaire resulted from the grouping of initial themes and sub-themes and from collaboration between the researcher and research participants. The quasi-final form of the questionnaire was then sent to the participants in the last focus group to harmonize views and obtain agreement on the final form of the questionnaire.

Research participants were informed about the purpose, objectives, and procedures of the study and the manner in which the confidentiality of the data collected was ensured. Participants signed the informed consent form prior to enrollment and were given the opportunity to withdraw from the study at any time. This study was approved by the Research Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy of Iași by Approval No. 103 of July 12, 2021.

RESULTS

In the first stage of the questionnaire design, data from the literature was used to develop the first version of the research questionnaire addressed to health care professionals caring for patients with a short prognosis.

The questionnaire was structured into three parts. The first part collects demographic data on the study participants; the second part explores the level of awareness of the concept of therapeutic obstinacy at the end of life and assesses the frequency of encountering such situations in daily practice; and the third part assesses the participants' opinions on some end-of-life interventions that may be considered disproportionate to the benefits obtained and the patients' quality of life. It also collects data on the perception of specialists regarding possible causes that may lead to situations of therapeutic obstinacy at the end of life and possible solutions to improve the situation.

The first version of the questionnaire was pretested in a pilot survey. The participants in the pilot survey were 14 nurses working in palliative care in two hospitals, one public and one private, in two different counties (Iași and Vaslui). Participants were invited to define their perceptions of the concept of end-of-life therapeutic obstinacy. Their responses were diverse and extremely interesting. "The refusal of the patient or his or her family to accept the situation, the hope of prolonging life at any cost, even at the expense of quality of life.", "Not knowing the prognosis of the disease can lead to demands from the family that bring no benefit to the patient (transfusions, infusions)", "The therapy prescribed is without effect and useless to the patient in the last days of life.", "By this concept, one can understand the refusal of the relatives to come to terms with the idea that nothing can be done about the patient's illness.", "The refusal of the patient or family to accept the fact that there comes a time when drug therapy no longer helps." "Refusal to accept the end of life".

The results obtained led to the organization of the first focus group interview, in which eight nurses working in the pallia-

tive care service of the Regional Institute of Oncology of Iași participated. Following this interview, it was considered necessary to reformulate some questions and introduce new ones considered to be relevant to the research in question. Thus, questions were introduced that explore the perception of specialists regarding the importance of psychological and spiritual preparation of patients in the process of accepting their prognosis, as well as the importance of psychological and spiritual preparation of medical staff as well as the patient's family for accepting the patient's death. It was also considered relevant to introduce a question on the most common wishes of patients at the end of life.

This new version of the questionnaire was pretested in a new pilot survey. Six nurses working in the palliative care service of the Regional Institute of Oncology of Iași participated in the second pilot survey, other than those in the previous pretest. The results of the pretest and this new version of the questionnaire were analyzed in the succeeding two focus groups. The second focus group was attended by 9 nurses (5 senior nurses and 4 nurses with more than 5 years' professional experience in the field) working in departments that also care for patients at the end of life: surgery, radiotherapy, oncology, and palliative care. Suggestions and comments from participants led to the following changes and additions:

• The system for quantifying respondents' level of agreement or disagreement according to the Likert scale was reformulated.

• The wording of the question on the assessment of the respondent's religiousness was clarified.

• The importance of responders expressing personal experiences (with relatives or close people) that might be classified as "therapeutic obstinacy at the end of life" was mentioned.

• The question highlighting possible pressure factors that lead to therapeutic obstinacy at the end of life was answered in several different ways: patient or family background (urban, rural, or diaspora; patient's religiosity; patient's ethnicity; pressure factors in society, including pressure from the patient's social status; non-recognition of the patient's terminal condition by medical staff; non-acceptance of the patient's terminal condition by medical staff.

• When asked about possible end-of-life medical interventions that may be considered disproportionate and futile in relation to the benefits obtained and the patient's quality of life, participants suggested supplementing the answer options with interventions such as: complex diagnostic investigations (CT/MRI/PET-CT); nasogastric intubation (NGS) for feeding; nasogastric (NG) tube insertion for hydration; use of existing NG tube for hydration and feeding; use of PEG/jejunostomy tube in the last days of life; feeding on previously inserted PEG tube; hydration on previously inserted PEG tube.

• Participants have emphasized the importance for the patient and family of choosing the place of end-of-life care for the patient.

The third focus group, organized as part of the research, comprised 11 physicians from different specialties (ICU, palliative care, oncology, radiotherapy, surgery, bioethics) with different professional ranks (university professor, university lecturer, senior lecturer, consultant physician). The role of this focus group was to analyze the

wording of the questions, their sequence, the link between the questions, and the content of the questions in relation to the research objectives. This led to the refinement of the research questionnaire and its final form. The suggestions offered in this focus group were:

• The demographic data collected was to be completed with the specialty of the responding physician. Thus, when analyzing the collected data, variations in response would also be observed based on medical specialty.

• The definition of "end of life" was clarified, suggesting the replacement of the phrase "last 72 hours of life" with "72-hour prognosis". Participants emphasized the relevance of the "72 hour" period for assessing interventions that may be considered disproportionate at the end of life in relation to the benefits and considered that a longer patient life span would create a non-homogeneous study group.

• When it comes to the question on the respondent's religiosity, participants suggested to also include the answer option "I do not wish to answer".

• The question about the respondent's personal experience with therapeutic obstinacy involving relatives, friends, or close persons was rephrased and clarified, and the connection to the question exploring the frequency of encountering such situations in professional work was created. It was considered appropriate and relevant to separate these two situations: personal experiences and professional experiences.

• When asked about the "first impression" of interventions that could be considered therapeutic end-of-life obstinacy, some non-aggressive interventions (e.g. oxygen therapy), and "traps" were also suggested to capture the degree of understanding the concept of therapeutic end-of-life obstinacy.

• When specifying pressure factors in situations of therapeutic obstinacy, a clearer division of the "patient age" factor was recommended, with a separate specification of age over 75 years, an age considered vulnerable in relation to certain medical interventions that may be considered aggressive in relation to the benefits.

• With regard to the pressure factor "patient's religiosity", it was decided to divide the situations into "religious patients" and "non-religious patients".

• Concerning possible causes of therapeutic obstinacy, it was suggested that the situation of "conspiracy of silence" be included, in which the patient or family does not know the diagnosis and/or prognosis of the disease due to the express wish of one of the parties involved (patient or family) in the process of communicating medical information.

• Fear of death was suggested as a possible cause of obstinacy, and the physician's fear of death was considered in addition to that of the patient and the patient's family.

DISCUSSION

End-of-life care raises ethical issues and could be a source of medical, ethical, and legal conflicts for physicians, lawyers, and ethics professionals. Physicians have no ethical or legal obligations to provide unnecessary treatment to the patient (34, 37-38). Despite the recognition among numerous medical experts of the phenomenon known as therapeutic obstinacy and its associated issues, it remains prevalent in routine clinical settings where patients are often subjected to such treatment, even when the therapy holds little possibility for

success (34-39).Given that the end of life is a unique phase in the course of life, previous studies have found that perceptions of therapeutic obstinacy highlight the difficult and challenging situation of providing end-of-life care (38-39). From our perspective, divergent opinions have the potential to foster diverse dialogues within a constructive setting that considers various viewpoints, personal experiences, and belief systems, ultimately culminating in a well-deliberated conclusion.

The focus groups organized to refine the questions in the research questionnaire collecting the perceptions of health care staff regarding therapeutic obstinacy at the end of life revealed that both nurses and physicians face this phenomenon, each reporting various causes and pressure factors leading to futile treatment at the end of life. Nurses stressed the importance for the patient and family of choosing the place of end-of-life care for the patient. The choice of place of care can be a pressure factor in end-of-life care. While home care was preferred in the past, today there is an increasing choice of care at this stage of life in medical facilities (40). The place of death is considered an indicator of the quality of care, with the decision on the choice of the place for end-of-life care influenced by economic, cultural, ethnic factors, medical literacy, patient values and beliefs. There is also evidence that the desire to die at home diminishes with age and poor health, the "hospitalization" of the end of life being now preferred (41).

Ivrin D. Yalom, a specialist in existential psychology, inspired by a serious study in the area of Greek philosophy and beyond and following a rich experience in psychotherapy, distinguishes several types of end-of-life and death reporting. The perspective of death is assumed differently according to gender, age, religiosity, culture, education, and profession (42). These variables express not only distinct perspectives but also life, spiritual, and professional experiences that give different grids of perception to the end of life. People who fall into various socio-professional categories experience anguish and fear of death in various ways. However, the same author shows that, in fact, it is not death itself that frightens us, but the meanings we attribute to it. Anguish in the face of death, therapeutic entanglements, the conspiracy of silence in the face of a grim diagnosis, and old age are all expressions of an assumed perspective on death and implicitly on life. Irvin D. Yalom shows that at play is a form of human narcissism that clings to us, to social and professional roles, and to those around us (42). Undoubtedly, this narcissism is greatly enhanced by the modern world and the technologies it makes available to us. Jean Twenge and Keith Campbell speak in this sense of a narcissism pandemic in the contemporary era that is based on the increase of self-esteem, the cult of celebrity, and technology development. Viewed from a broader, interdisciplinary perspective, the answers received reflect the new social and cultural context in which new meanings of death are developing. This, because the collective imagination is focused only on a certain perspective on existence, a perspective in which death is hidden, becomes an out-of-date topic, dispatched from our daily concerns. Moreover, developments in medicine and new technologies promise the extension of life and bring into question concepts such as the death of death (43).

The nurses participating in the focus groups considered it relevant to the research if the respondents to the question-

naire indicated their degree of religiosity or faith. The literature mentions that the nurse's religious beliefs can enhance the nurse's clinical experience, obviously without the nurse trying to impose his or her own beliefs on the patient. End-of-life care evokes personal religious values for both nurse and patient (44). The physicians participating in the focus group also considered the questioning on religiosity relevant, both with regard to the questionnaire respondent and the patient at the end of life, the latter being considered a possible pressure factor regarding therapeutic obstinacy at the end of life (45). With regard to medical interventions that may be considered disproportionate and futile at the end of life, both nurses and physicians proposed a number of interventions that respondents to the questionnaire could rate according to the extent to which they could be assessed as therapeutic obstinacy at the end of life. These types of interventions are in line with the literature, which most frequently subjects to ethical debate the appropriateness of initiating or not initiating artificial nutrition and hydration, ventilation, antibiotherapy, chemotherapy, any surgical intervention, dialysis, diagnostic and therapeutic interventions, cardiopulmonary resuscitation, mechanical ventilation, mechanical circulatory support, discontinuation, and withdrawal of treatment at the end of life (23-24, 46-47).

Physicians' fear of death was proposed by physicians in the third focus group to be assessed by study participants as to what extent it constituted a pressure factor for therapeutic obstinacy at the end of life. Although medicine has long ignored this fear, the literature notes that fear of death prevents health professionals from providing good and compassionate care to patients at the end of life (48). Lack of knowledge of the wishes and preferences of the patient and their family members was proposed for assessment as a possible cause of therapeutic obstinacy at the end of life. Aghabarary *et al*. highlighted that lack of knowledge of patient wishes by medical staff and the patient's family were key pressure factors in the provision of futile treatments at the end of life (39).

The pressure put on caregivers by family members who, for a variety of reasons, demand futile care was another potential therapeutic obstinacy at the end of life that both nurses and doctors participating in the focus groups considered crucial to include in the research. Chamberlin *et al*. showed that futile or potentially inappropriate care is associated with physicians avoiding family members, which is the behavior most strongly associated with burnout (49).

When it comes to assessing the frequency of facing the pressure of end-of-life therapeutic obstinacy in everyday practice, the medical staff decided to include this assessment in the questionnaire. Leuter *et al*. identified an internal struggle among healthcare professionals who felt compelled to perform treatments they believed to be ineffective (50). Results showed that nurses and physicians had different perspectives on morally sensitive circumstances in healthcare activities, which was likely related to differences in training, roles, and accountability to patients and healthcare institutions.

Psycho-emotional and spiritual support for the patient at the end of life, for their family, as well as for the healthcare staff involved in their care, are considered important in end-of-life care. Palliative care is one that provides holistic care for the patient and his or her family, adding psychological, social, and spiritual dimensions to

the physical one as recommended by palliative care guidelines. Spirituality is considered a priority for patients with life-threatening illnesses because of their hopelessness in the face of death and fear of the unknown. Psycho-emotional and spiritual support at the end of life gives a sense of comfort and security to patients and their families and helps to defuse some religious or non-religious attitudes, with healthcare professionals playing an important role in this supportive care (45).

The questionnaire items also identified in the literature reflecting the causes and pressure factors of therapeutic obstinacy at the end of life were supplemented with items reflecting the social, cultural, and medical particularities of our country. Both nurses and physicians identified the attitudes and demands of some patients and caregivers considered to be important members of society as a pressure factor in these situations. It was also proposed to evaluate the differences in attitudes between patients and caregivers from rural and urban areas from this point of view. The question at the end of the questionnaire gives the researcher the opportunity to explore the most common wishes expressed by patients at the end of life, information that may provide new ideas for further research in this area.

The resulting questionnaire will be self-administered, without the need for the researcher to be physically present, and will be sent both online via the internet and in hard copy on paper, along with instructions for filling out the questionnaire and consenting to participate in the research.

Strengths and limitations of this study

Strengths: the questionnaire created collects the views of health care staff on end-of-life therapeutic obstinacy, being the first questionnaire of this type created in Romania and appropriate to the cultural factors in this country. It explores the degree of knowledge and perception of medical staff of the concept of therapeutic obstinacy at the end of life, assesses the frequency of encountering such situations in everyday medical practice, and evaluates the opinion on some end-of-life interventions that may be considered disproportionate to the benefits obtained and the quality of life of patients. It also collects data on specialists' perceptions of possible causes that may lead to situations of therapeutic obstinacy at the end of life and possible solutions to improve such situations.

Limitations of the study: although the questionnaire explores many dimensions of therapeutic obstinacy at the end of life, it does not capture the effects of the phenomenon on healthcare professionals or the impact on end-of-life care.

CONCLUSIONS

Treatments that improve the patient's well-being and minimize the suffering of the patient and family are just as important as those designed to save the patient's life. Even though therapeutic obstinacy and medical futility have been recognized in medical practice for at least two decades, they continue today, with a detrimental impact on patients and their families, healthcare professionals, and the healthcare system. The reasons for discouraging or reducing therapeutic obstinacy at the end of life are simultaneously clinical, ethical, and economic. However, this discouragement has proved difficult because of public expectations of what medicine can achieve as well as because of professionals' percep-

tions of ethical and legal requirements.

The questionnaire created is innovative and the first of its kind in Romania. The structure of the questionnaire includes items resulted from the literature as well as new items identified by the medical professionals participating in the research, which allow the questionnaire to be adapted to the social, cultural, and medical conditions in this country. The data collected by means of this tool can provide important information and arguments for debating ethical, medical, legal, and economic issues related to end-of-life care, for assessing the behavioral and organizational trends of the actors involved in this type of care, and for capitalizing on the ideas of professionals in balancing the management of these patients.

Directions for future research

The present questionnaire does not encompass the collection of data pertaining to the impact of therapeutic obstinacy on healthcare personnel, the healthcare system, or the patient and their family. The findings obtained from this questionnaire can serve as a valuable foundation for conducting further study in this area. Finally, it is critical to explore the perspectives of patients and their families on medical interventions at the end of life, as well as the factors influencing decision-making in medical care in the final days of life. Our findings pave the way for a multidisciplinary approach to a variety of end-of-life treatments and therapies. This would imply the creation of complementary therapies that combine medical, psychological, and spiritual therapies.

CONFLICTS OF INTEREST AND FUNDING

The authors declare no conflict of interest. This research received no external funding.

INSTITUTIONAL REVIEW BOARD STATEMENT

The study was conducted in accordance with the Declaration of Helsinki, and approved by the Research Ethics Committee of "Grigore T. Popa" University of Medicine and Pharmacy of Iași, by approval no. 103 of 12th of July 2021. The final form of the administered questionnaire is available by request addressed to the authors.

INFORMED CONSENT STATEMENT

Informed consent was obtained from all subjects involved in the study.

PRELIMINARY FINDINGS ON THE EFFECT OF VITAMIN B_6 ON ZEBRAFISH SOCIAL BEHAVIOR (Abstract): Vitamin B_6 (vit. B_6) is one of the most important vitamins involved in the maintenance and promotion of a good state of health and body function. Needed in multiple processes, vit. B6 is a water-soluble vitamin that actively participates in hemoglobin formation, glycogenolysis, gluconeogenesis, and the immune system. Its deficiency was many times addressed and linked with serious health issues. Some studies claim that vit. B_6 could be considered an adequate treatment for autism spectrum disorder (ASD). Usually seen as a complex neurodevelopmental disorder, ASD is a long-life condition described by persistent challenges in social communication and interaction, aside from restricted interests and repetitive behavior. It is widely recognized that genetic predisposition is one of the primary risk factors for ASD; however, environmental factors should also be explored due to their particular and complex mechanisms. **Materials and methods:** The main goal of the present study was to determine the effect of vit. B_6 on zebrafish behavior as an animal model for ASD using valproic acid (VPA), an anticonvulsant drug. For a period of five days, fish were exposed to 100 µM vit. B_6, 300 µM VPA, and a mixture of 100 µM vit. B_6 and 300 µM VPA. All the behavioral parameters were quantified through the EthoVision XT 11.5 software and performed using the adapted T-maze. The time spent in left arm, where the social stimulus was added, reflected the zebrafish's sociability level. Besides, data from locomotor activity was gathered. **Results:** No significant effect on social behavior was revealed after five days of exposure to vit. B_6. Despite this, behavioral improvements were observed in groups where fish received vit. B_6. **Conclusions:** Overall, this study provided limited evidence regarding the vitamin's capacity, suggesting the necessity of additional studies to promote the efficiency of vitamin usage in ASD. **Keywords:** VITAMIN B_6, ZEBRAFISH, SOCIAL INTERACTION TEST.

Described for the first time in 1932, vitamin B_6 (vit. B_6) comes from the wide group of B vitamins (1). Over time, its role and implications in various metabolic, physiological, and developmental processes were discovered. Due to its high solubility in

water and the incapacity of humans or other mammals to synthesize it, vit. B_6 can't be stored in the body, and inadequate diet can lead to important health issues. In general, vit. B_6 presents six vitamers, such as: pyridoxine, pyridoxal, pyridoxamine, and its bioactive 5'-phosphate forms: pyridoxine-5'-phosphate, pyridoxal-5'-phosphate, and pyridoxamine-5'-phosphate (2-4). Known to be part of more than one hundred body processes, vit. B_6 has been reported to act on protein folding, the biosynthesis of amino acids, glycogen mobilization, and neurotransmitter biosynthesis (5). Moreover, it was shown that vitamers of vit. B_6 can actively participate in the stress response through the antioxidant capacity proven against endogenous and exogenous sources (4,5). As a consequence of the stress presence, at cellular level, various metabolic products with negative impacts can appear, usually named free radicals (6, 7). Another important implication of vit. B_6 is in the process of erythropoiesis by participating in the addition of iron to the protoporphyrin that is related to theme synthesis (8).

Regarding the nutritional status of vit. B_6, this requires attention in assessing the optimal intakes. For instance, serious health problems were mentioned for its deficiency or even for elevated vitamin levels. Due to the metabolic roles played by the active form of vit. B_6, namely the pyridoxal-5'-phosphate (PLP), it can intervene in the mechanisms of different diseases and symptoms as: microcytic anemia, convulsions, dermatitis, diabetes, immunity, inflammation, or cardiovascular diseases are some of it (9, 10). In addition, connections between neurological conditions and vitamin's deficiency were highlighted in several works. One of the common conditions is represented by peripheral neuropathy, a disease characterized by nerve damage situated outside the brain and spinal cord (11). Insufficient levels of vit. B_6 were also linked to impaired production of neurotransmitters like serotonin, dopamine, γ-aminobutyric acid (GABA), noradrenalin, histamine, glycine, and d-serine (12, 13). Being involved in the synthesis of GABA, vitamin's deficiency can result in impaired neurotransmitter production that lowers the seizure threshold due to the GABA-mediated inhibition. A work from 2018 reported low levels of vitamins and high levels of GABA in a clinical study about depression (14). Similar data was shown for the autism spectrum disorder (ASD) where increased GABA levels were recorded (15-17).

The current description of ASD refers to it as a neurodevelopmental disorder diagnosed based on clinical observations regarding social deficits and repetitive behaviors (18-20). With no cure discovered and with multiple behavioral interventions, ASD is defined as a multi-factorial and complex disorder that can be identified since early childhood (20-22). Accumulated findings suggest that there is a connection between vit. B_6 and autism. The latest work published (2024) indicates that there is no causality between vit. B_6 and ASD risk after applying the Mendelian randomization (23). Despite this, a bunch of works are pointing out a possible implication of vit. B_6 deficiency in the sustaining and promotion of ASD-like symptoms in humans, but also in animal models (24,25). On the other hand, supplementation of the diet with vit. B_6 or combined doses of vit. B_6 with magnesium indicated a favorable response in several clinical studies (26-30).

In order to investigate the possible influence of vit. B_6 in an ASD context, the present work used zebrafish as an animal model. Zebrafish or *Danio rerio,* is a tropical fish brought for the first time to the

research world by George Streisinger in 1981 (31). This is a well-known organism that has been strongly utilized in the last few decades due to its advantages for biomedical and translational research (32-35). Its genome similarity and complex repertoire of behaviors make zebrafish a suitable model for investigating human diseases. It has been demonstrated that zebrafish can display specific-ASD symptoms that are directly related to social domain and repetitive behavior (36-39). Genetically or chemically-induced, autistic-like features could be generated in zebrafish models and further investigated with promising results for mechanisms and treatment discoveries (40-43). For the current work, valproic acid (VPA) was used to generate the ASD model in zebrafish; model which was several times mentioned in literature reports (44-46). This compound is prescribed for the treatment of epilepsy, bipolar disorder, and other types of brain seizures (47).

Nevertheless, the present experimental study aimed to investigate the short-term effects of the vit. B_6 and VPA on zebrafish from a behavioral perspective. The social interaction test brought few findings that required extra exploration of the current hypothesis due to obvious limitations that could be discussed in future works.

MATERIALS AND METHODS

Test organism

Zebrafish (*Danio rerio*) of the WT line (± 0.23 g weight, 26 mm body length) were purchased in a number of 150 animals and acclimatized for three weeks to the laboratory environment. The housing tank was filled with dechlorinated tap water that was maintained at a temperature of ± 26°C, a pH of 7.5, 90.6% dissolved oxygen, and a salinity of 0.25. The circadian rhythm was kept by an automatic timer set to 14: 10 hours (light: dark). Similar conditions were assured for the experimental tanks. Fish were fed twice a day with TetraMin flakes (5% of body weight in food per day, of which vit. B_6 accounted for approximately 12 ppm).

Substances

Valproic acid (P4543-100g) was bought from Sigma-Aldrich as a powder with a purity of 97.5%. For this study, 300 µM was chosen as the test dose, which was obtained by dissolving a certain amount of the stock solution into the medium. Regarding vit. B_6, this was provided by a local pharmacy as a diet supplement (the product brand will remain anonymous due to ethics and conflicting interests). Beside pyridoxine hydrochloride, the liquid product also contained purified water, glycerol, and potassium sorbate. For this study, 100 µM vit. B_6 was selected based on previous data (unpublished).

Experimental design

The first step in the present study consisted of the acclimatization of fish to laboratory conditions for a period of three weeks. After this time, ten zebrafish were randomly selected (a sex ratio of 1:1), and transferred to the experimental tanks, where animals were permitted to adapt to the new space. Four groups were formed, such as: control group, vit. B_6 group, VPA group, and the last group exposed to both chemicals (vitamin and VPA). Each tank (30 cm long × 16.5 cm wide × 20 cm height) had a capacity of 5 L and was equipped with an air pump. Secondly, the initial behavior of each group was assessed by social interaction test that were again performed on the first and fifth days of exposure. Fish from the VPA and mixture groups were constantly exposed to the anticonvulsant drug, while the exposure to vitamin lasted only one hour. This

method was adapted after the protocol of Pena *et al*. (48). Fish were moved to plastic vials filled with vitamin solution and kept for one hour. The control and VPA groups simulated vitamin exposure; its vials were filled with clean water. Behavioral testing started at 10 a.m. after finishing the vitamin's exposure. In the end of the experiment, fish were killed by immersion in cold water (< 4°C), and deposited in the freezer at - 80°C.

Social interaction test

The social interaction test aimed to quantify the changes that can appear in the sociability of zebrafish. For this test, the Noldus maze was adapted and transformed into a T-maze (three arms and a start point). A transparent wall was placed in the left arm to divide an area that will be dedicated to the social stimulus (fig. 1). Usually, this stimulus is represented by a group of 2-3 conspecifics. Each fish was placed at the start point for 30 seconds and recorded for the following 4 minutes. The total distance moved, the average velocity, the active time, and the time spent in arms were measured.

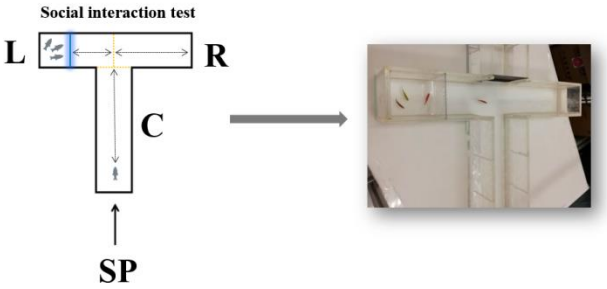

Fig. 1. The design of the social interaction test adapted for the Noldus maze transformed into a T-maze with three arms: left (L), right (R), and center (C) and an established start point (SP) situated in the center arm.

Statistical analysis

The behavioral parameters analyzed in this study were recorded through the EthoVision XT 11.5 software and sorted using the Excel files from the Microsoft Package (Microsoft Office Professional Plus 2021). All the statistical analysis was performed using the OriginPro v.9.8 software (OriginLab Corporation, Northampton, MA, USA, 2021). Data was tested for normality with the Shapiro-Wilk test (α was set at 0.05). A one-way ANOVA followed by a Tukey's multiple comparisons test was applied when the data checked the normal distribution. The results shown are presented as mean ± standard error of the mean (SEM), with $p \leq 0.05$ regarded as statistically significant. The graphical illustration of the results was made using the same statistical software.

Ethical note

This study was approved by the Ethics Committee of the Faculty of Biology, "Alexandru Ioan Cuza" University of Iasi, with registration number 342/09.02.2023. Also, the recommendations from Directive 2010/63/EU of the European Parliament and those of the Council of 22 September 2010 regarding housing, utilization, and protection of animals used for scientific purposes were followed.

RESULTS

No significant changes were recorded for the locomotor parameters evaluated during the social interaction test ($p > 0.05$ ANOVA, Tukey). The group exposed only to 100 µM of vit. B_6 did not exhibit any important improvements after one day (965.5 ± 87.9) or even in the last day of the exposure (860.9 ± 71.1) when compared to the initial behavior (962.2 ± 87.3). Moreover, combined exposure to 100 µM of vit. B_6 and 300 µM of VPA presented a similar trend, but on the last day, the distance moved maintained an appropriate value as recorded on the first day of exposure (863.1 ± 62.7 vs. 862.2 ± 79.1). Also, a slight decrease in the distance was recorded for the VPA group on the last day (868.3 ± 94.6) compared to the first day (1004.5 ± 86.2) and initial behavior (1009.9 ± 101.7) (fig. 2 left). Similar trends were observed for the average velocity parameter (Fig. 2, middle). Regarding the active time spent by the fish moving, its activity decreased on the last day of the experiment, while interestingly, the mixture group demonstrated almost the same activity seen in the initial behavior stage and first day of exposure (fig. 3, right).

In regards to the hypothesis of the present study, it could be seen from Fig. 4 that vitamin generated a short-term effect on the experimental groups, especially on the social behavior. Time spent in the left arm, where the social stimulus was added, presented the most significant activity compared to other arms. The group exposed only to vit. B_6 showed an increase in the time spent (65.2 ± 8.9 %), data similar to the observed behavior in the initial phase (68.6 ± 8.2 %), even if in the first day of exposure, time decreased (55.6 ± 8.1%). When vitamin was added in the VPA group, time spent in the area of the social stimulus increased, recording on the last day a value higher than that from pretreatment (59.9 ± 6.7 %) and the first day (50.7 ± 7.1 %) versus 66.5 ± 5.8 % (Fig. 4 left). After one day exposure to VPA, fish tended to spend more time in the left arm (61.3 ± 6.5 %) in comparison to initial behavior (50.3 ± 7.3 %) and the last day (42.7 ± 9.3 %). No trends were seen in the case of the control group.

Compared to the left arm, the other two arms did not record as much activity that was observed in the area dedicated to the social stimulus (Fig. 4 and Fig. 5). The second preference expressed by the experimental groups was different for each day; center arm for the initial behavior and the last day of the experiment, while the right arm was chosen for the first day by all the groups.

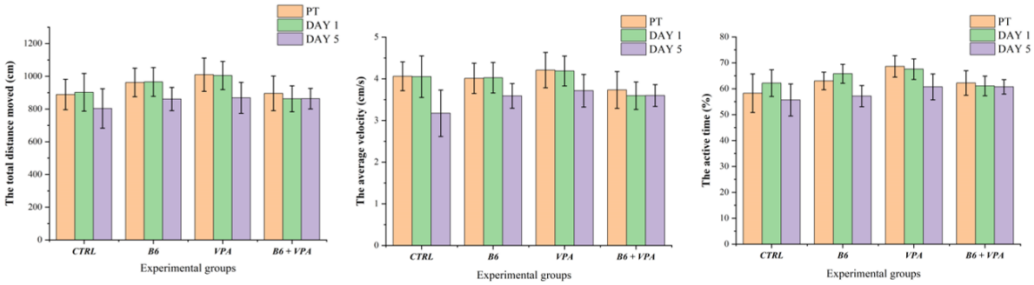

Fig. 2. The locomotor activity parameters recorded during the social interaction test of the experimental groups (n= 10): the total distance moved (left), the average velocity (middle), and the active time (right) during five days of exposure to vit. B_6 and VPA. PT stands for the pretreatment period. Data are expressed as mean ± SEM.

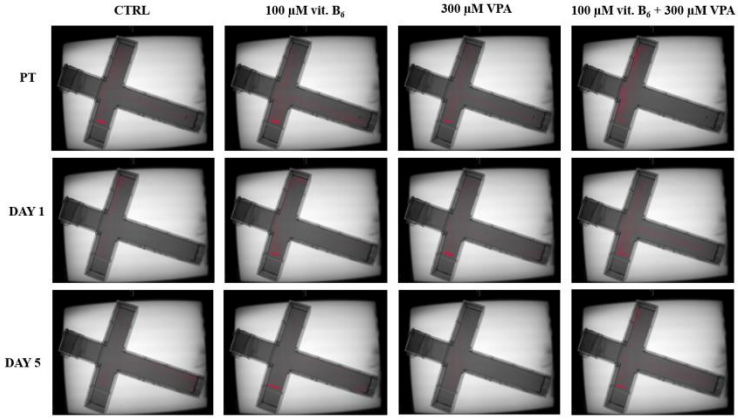

Fig. 3. The track visualization recorded during the social interaction test of the experimental groups where the left arm had the social stimulus added and was the most visited compared to the right and center arms.

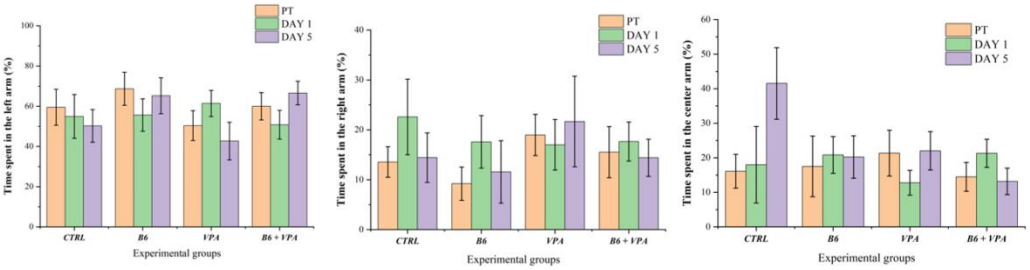

Fig. 4. The time spent in the T-maze arms recorded during the social interaction test of the experimental groups (n= 10): left arm (left), right arm (middle), and center arm (right) during five days of exposure to vit. B_6 and VPA. PT stands for pretreatment period. Data are expressed as mean ± SEM.

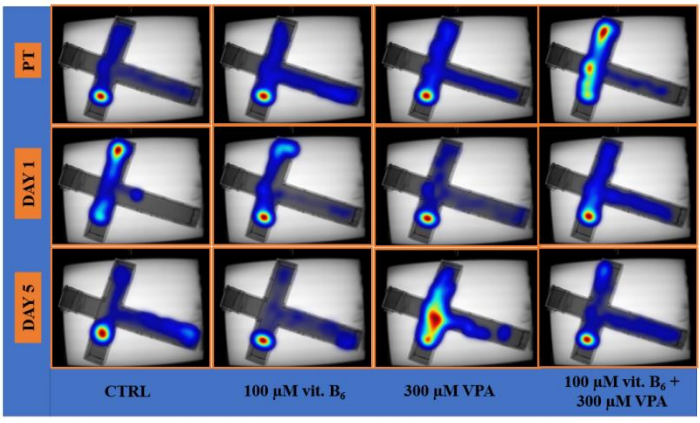

Fig. 5. The time spent in the T-maze arms recorded during the social interaction test of the experimental groups was presented through heatmaps for all testing days.

DISCUSSION

The current experimental study focused on analyzing the influence of vit. B_6 on social behavior in an ASD animal model using VPA as an inductor agent in a short-time exposure. As was expected, no significant data was obtained after five days of exposure to vitamin and VPA. Despite this fact, certain trends were perceived for all the exposed groups, mainly the time spent in the left arm next to the stimulus. In this way, the preliminary findings revealed the tendency of fish exposed to 100 µM vit. B_6 to return to the initial behavior in an established stress condition, while single exposure to 300 µM VPA triggered a lower sociability after five days. This experimental period, the sub-chronic type, could represent one of the main limitations of this study. In general, the effectiveness of vitamin supplementation requires a longer period, as was shown by Adams *et al*. in a research survey regarding vitamin and mineral supplementation for autistic people. A period of 5-8 weeks was necessary to observe improvements in autistic symptoms, and more than 90 % reported good evolution after 9-12 weeks of treatment, as stated by the NSTEA scale (49).

Diagnosed based on two main criteria, ASD is one of the neurodevelopmental disorders that expresses high variability and complexity due to its multifactorial character (50). It is known that genetic predisposition plays a major part in the occurrence of ASD, but the dynamic interactions with certain environmental risk factors leads to a multitude of combinations, highlighting the uniqueness of this disorder (20). With no cure discovered, research on this subject is abundant but still requires knowledge. Although there are several therapeutic tools that have proven its efficacy, vitamin supplementation is still uncertain due to the lack of clinical studies. For example, Adams *et al*. showed that autistic children who were not on a vit. B_6 supplementation revealed high plasma levels of vitamin and it was suggested that pyridoxal kinase responsible for producing the active form, PLP, was impaired and, consequently, had higher levels of PLP (5,51). Several years later, this hypothesis was disproved by the study of Chelban *et al*. which demonstrated high responsiveness from autistic people who received PLP as a supplement (52).

Another limitation of the present work is the absence of GABA measurement, especially of the direct correlation that might be suggested between it. This comes as a "consequence" of the involvement of vit. B_6 in the neurotransmitter system by its participation in some molecules biosynthesis (13). In ASD cases, based on magnetic resonance spectroscopy, neuroimaging, enzyme-linked immunosorbent assay, and postmortem brain analysis, it is often reported that there are disturbances of the GABA neurotransmitter, such as altered GABA metabolites, a lower ratio of GABA/ glutamate, and lower GABA levels (17, 53-55). Acting as co-factor, vit. B_6 regulates the GABA's activity, and it was indicated that supplementation with vit. B_6 led to increases in GABA levels in a clinical trial for anxiety and depression. The Screen for Adult Anxiety Related Disorders (SCAARED) and the Mood and Feelings Questionnaire (MFQ) tests concluded that vitamin intake could reduce anxiety and improve people's mental state (56).

It can be suggested that VPA might act on the GABA neurotransmitter, but reports are underlying the capacity of VPA to stimulate neurotransmitter production,

which contradicts the existence of a negative impact in some cases (57, 58). Thus, administration of VPA might lead to Parkinson's disease by stopping the voltage-gated ion channels and inhibiting histone deacetylases, for instance (59). Prenatal and neonatal exposure to VPA proved to be an autistic-like inductor in humans and in different animal models (40, 46, 60, 61). The results of this study did not point out significant changes in the total distance moved, average velocity, and active time. Despite this, in the last day of the experiment, it was observed that the fish had the tendency to lower the activity of all the parameters mentioned above compared to the group that also received vit. B_6. In zebrafish studies, early exposure to VPA was linked with hyperactivity, ASD-like symptoms, and impaired sleep behavior (60, 62-64).

Regarding the deficiency of vit. B_6 in zebrafish, the literature lacks in offering too much information. A study from 2019 that investigated neonatal epileptic encephalopathy in zebrafish proved the vitamin's effectiveness in alleviating the morphological and behavioral alterations (65). Pyridox(am)ine 5′-phosphate oxidase (Pnpo) deficiency was evaluated in Pnpo deficient zebrafish, known to be able of inducing serious seizures and neurodevelopmental issues. Early administration of PLP to zebrafish larvae that were Pnpo deficient led to an increase in the survival rate and PLP, glutamate, glycine, and GABA levels after 20 days (66). In a recent study on rats it was shown that vit. B_6 deficiency was able to lead to the appearance of autism-like behaviors in rats through autophagy; a process that was mediated by the inhibition of the mammalian target of rapamycin (mTOR). Moreover, the number of social interactions decreased, along with self-grooming time and bowel frequency, in the rats with insufficient vitamin compared to the control or supplemented group (25). This alteration occurred in the mTOR pathway and was often linked with autism pathology, being the one involved in synaptogenesis regulation, corticogenesis, and other neuronal functions (67-70). Additionally, this perturbation can lead to various negative outcomes, such as: abnormal synapse formation and brain structure, neuroinflammation and oxidative stress, or even mitochondrial dysfunction in different brain areas (70). All these processes mentioned above were associated with significant changes in autistic people that were summarized in impairments in social domain, communication, and behavior when, concomitantly, mTOR was hyperactivated (70, 71).

Beside the common symptoms reported in ASD, disruptions of the gastrointestinal tract and microbiota composition were highlighted several times (72-74). Interestingly, the work of Li *et al*., demonstrated that deletion of EphB6 (a pseudo kinase) can lead to autistic-like features alongside microbial disturbance in mice as a model animal for ASD (24). Improvements in social behavior were observed when vit. B_6 was intraperitoneally injected into EphB6-deficient mice. Moreover, transplantation of the fecal microbiota from wild type mice resulted in an increase of vit. B_6 in the plasma (24). The latest data published that focused on the gut-brain axis showed a powerful connection between different ASD phenotypes and temporal changes in the microbial composition (75). Although there is no direct or indirect established link for gut microbiota as risk factor in generating ASD, evidence serves both di-

rections. So, disturbances of microbial composition and of its metabolite levels were noticed and brought out not only for the gastrointestinal system but also for ASD (24, 74, 76).

As a final direction of this work could be to mention the vitamin's role as antioxidant. Restoring the social behavior of zebrafish after exposure to VPA might be assigned to vit. B_6 influence in a developed stress environment. One of the proposed mechanisms by which VPA induces toxicity is through the presence of oxidative stress (77-79). Autistic symptoms and cellular changes appeared as a consequence of VPA administration in rats, but it were improved after exposure to a combined extract of purple rice and silkworm pupae (78). Another study on rats looked at the VPA effect and found increased anxiety, hyperactivity, elevated activity for acetylcholinesterase, and decreased activities for superoxide dismutase and glutathione, besides displaying autistic-like features (80). The potential of vit. B_6 against the effects generated by VPA was revealed after a seven days treatment in male rats. The vitamin acted in a positive way on the oxidative stress-specific markers by decreasing the activities of glutathione-S-transferase, glutathione peroxidase, and glutathione reductase and increasing superoxide dismutase (81, 82). The direct correlation between VPA and oxidative stress, along with the effectiveness of vit. B_6 in fighting against free radicals through antioxidant sustenance, could be further explored since the involvement of oxidative stress in ASD appearance is certain.

CONCLUSIONS

This experimental study shows that exposure to vit. B_6 could have a positive impact on the social behavior of zebrafish based on the preliminary data obtained. Although no significant changes were seen in locomotor activity, vitamin supplementation in a stressful condition was helpful, highlighting the vitamin's capacity to act as an antioxidant. Furthermore, due to its limitations (time of exposure, the used vitamin supplement, or the way of exposure), the noted findings could draw future pathways of investigation by exploring the vitamin's influence in an ASD context.

CONFLICT OF INTEREST

The authors declare no conflict of interest.

ACKNOWLEDGMENTS

This work is part of Madalina-Andreea Robea postdoctoral research and was co-funded from the European Social Fund through Operational Programme Human Capital 2014-2020, <<Educational and training support for PhD students and young researchers in preparation for insertion into the labor market>>, POCU/993/6/13/153322. Also, a part of the current results were presented at the Neurology World Conference (September 2023).

EVALUATION OF DEMENTIA-TYPE COGNITIVE DECLINE THROUGH 18F-FDG PET-CT QUANTIFICATION AND CORRELATIONS OF THE MMSE TEST WITH FUNCTIONAL IMAGING BIOMARKERS (Abstract): Recognition of the given moment when a mild cognitive impairment (MCI) converts to Alzheimer's Disease (AD) represents a turning point in the assessment of the mental status rate of decline, but is still insufficiently systematically studied. Our aim was to contribute to the identification of the dementia irreversible starting point by cognitive assessment test Mini Mental State Examination (MMSE) and correlating it with the hybrid imaging technique positron emission tomography (PET) with fluor-18 fluorodeoxyglucose (^{18}F-FDG) combined with localization computed tomography imaging (PET/CT), emphasizing that the method of quantification is crucial for patient evaluation and regression analysis can be helpful. **Materials and methods:** We studied 30 patients aged between 22 and 76 years presented during the assessment of their oncological pathologies. We evaluated their cognitive status by a MMSE test. All patients underwent a ^{18}F-FDG PET/CT examination, the image acquisition including the brain region. After specific image processing, characteristic regions of interest (ROIs) were identified, maximum and mean standardized values (SUVmax and SUVmean) were extracted. We computed correlations between 17 variables including: age, MMSE score value, glycemia, Administered Radiopharmaceutical Dose, Uptake Period, SUVmax and SUVmean for numerous ROIs as cerebral (SUVmaxCC) and cerebellar cortex (SUVmaxCc), posterior cingulate gyrus (SUVmaxPCG) and precuneus (SUVmaxP), as well as two SUV ratios: SUVRPCG and SUVRP. Calculation of mean, minimum, maximum and standard deviation have been made for each variable, and calculation of 4 regression functions (linear, exponential, power and logarithmic) and unique correlation analysis have been made for each pair of variables. **Results:** MMSE tests identified values of over 24, with an average of 28.07 ± 1.5DS, all patients examined having a normal cognitive status. SUVmaxPCG had values between 5.1 and 21.3 g/mL, with an average of 13.36 ± 3.77DS, SUVmeanPCG between 4 and 13.2 g/mL, average 8.68±2.35DS, and SUVmaxP between 4.8 and 21 g/mL with an average of 13.06 ± 3.81DS,

SUVmeanP between 4.1 and 14.1 g/mL with an average of 9.93±2.73DS. From the 34 strong and very strong linear and exponential correlations identified between SUVs of the studied ROIs, 7 correlations have "extremely strong" values (R>0.925) including SUVs of AD cerebral specific ROIs. Also, there is a mean linear correlation between Age and MMSE score (R=0.57). **Conclusions:** Quantitative evaluation of ^{18}F-FDG PET-CT images for patients with neoplasia, found in a stage when an MCI can evolve simultaneously, could bring useful information for a possible early AD diagnostic and would be advisable in the precision medicine of the brain cognitive status evaluation. **Keywords**: COGNITIVE DECLINE, MILD COGNITIVE IMPAIRMENT (MCI), MMSE, PET/CT, IMAGING BIOMARKERS.

INTRODUCTION

Alzheimer's disease (AD) is the most common form of dementia, describing 60-70% of cases and affecting approximately 50 million of people worldwide, with an increasing incidence that could triple in the next 30 years, according to the World Health Organization in Guidelines for Risk Reduction of Cognitive Decline and Dementia (1). The adult process of neurogenesis is altered in the earliest stages of the disease, by progressive and irreversible loss of memory, of higher cerebral functions and later, of the self-help skill (2). Consistent with current guidelines, the diagnosis of AD involves clinical evidence of cognitive impairment, imagistic changes and accumulation of intracerebral biomarkers (3).

The brain has the highest avidity for glucose, consuming about 20% of the energy derived from its metabolism. But, in amnestic mild cognitive impairment (aMCI) and in AD, glucose metabolism is dramatically decreased, partly due to oxidative damage of enzymes involved in glycolysis, in tricarboxylic acid cycle and in adenosine triphosphate (ATP) biosynthesis, resulting synaptic dysfunction and neuronal death and thus the thinning of important areas of the cerebral cortex (4, 5, 6).

Neuroimaging, in particular hybrid functional and structural imaging, Single-photon Emission Computed Tomography (SPECT) or Positron Emission Tomography (PET) with various radiotracers currently available, in combination with Computed Tomography (CT) or Magnetic Resonance Imaging (MRI), are complementary medical imaging techniques and essential tools for in vivo studies of neurocognitive disorders and especially of AD. While CT and specifically MRI provide cerebral structural information with a higher resolution (hippocampal volume reduction and loss of other structures from the temporal lobes, with neurodegeneration and tissue loss), PET imaging can provide metabolic and molecular information of the brain, with high sensitivity, by mapping the distribution of glucidic metabolism (decreased glucose avidity and neurodegeneration in the temporoparietal cortex, posterior cingulate gyrus and precuneus), of NFTs and βA deposits in the cerebral cortex, from the presymptomatic to the dementia stage (7, 8, 9, 10). The brain areas strictly involved in cognitive decline, the posterior cingulate cortex and the precuneus, are known to represent the first areas of metabolic alterations, that precede cognitive symptoms for patients with dementia and especially with AD.

aMCI is a clinical precursor of AD but only some patients at the respective stage will progress to irreversible AD. Recent

studies have shown that PET examination with the analog radiotracer of fluorine-18 fluorodeoxyglucose (18F-FDG PET) can detect prodromal AD and can highlight the progressive conversion of aMCI to AD with an accuracy of 89%, in a follow-up time of minimum 5 years. (11).

Histopathological changes such as amyloid β plaques (βA), neurofibrillary tangles of tau proteins (NFTs) and neuritic plaques precede symptomatology by more than a decade, during which treatment may be effective in slowing or even stopping the progression of the disease (12). Thus, in addition to serum biochemical markers (cerebral acetylcholinesterase, superoxide dismutase, glutathione peroxidase, catalase, total content of reduced glutathione, carbonyl protein and malondialdehyde and lactate dehydrogenase) and from cerebrospinal fluid (low or inadequate concentrations of βA fractions and increases in the concentration of hyperphosphorylated tau proteins) (6, 13), as well as the imaging markers mentioned above, other accessible and very effective methods, such as those of mathematical statistics, could help in the early diagnosis of the disease.

Assessing mental status and its rate of decline for a given population are still insufficiently studied issues. Cognitive assessment tests such as Mini-Mental State Examination (MMSE), involving the rapid assessment of time and space orientation skills, attention and calculation, comprehension, naming, repetition, memorization and reminder, reading, writing and drawing, are widely used methods for clinical monitoring of cognitive abilities in the elderly, but insufficient to assess the progression of dementia (14).

Although data from literature emphasize the importance of quantitative evaluation of brain metabolism (4, 5, 6, 11, 12, 19, 20, 21, 22), the optimal method and the relationship between different methods that can be used in this regard have not yet been established and studies are still needed, each one bringing different information about the pathophysiology of AD development. In this context, this paper proposes a detailed study of data obtained for the cognitive and metabolic status of patients with potential cognitive decline to AD by the most used hybrid imaging technique PET/CT, qualitative and quantitative processing of functional metabolic images using specific software tools, their correlation with classic MMSE tests and statistical processing of obtained data. The novelty of the study is the combined analysis by specific methods and statistics of data obtained by MMSE and by 18F-FDG PET/CT, allowing correlations of special significance for patients with aMCI.

MATERIALS AND METHODS

For this pilot study, we prospectively evaluated 30 patients from the Regional Institute of Oncology Iasi, Romania, known with various oncological pathologies and undergoing a PET/CT examination. The inclusion criteria included: adult patients hospitalized in the Regional Oncology Institute, Iasi, Romania, in the period June-July 2021, which have a recommendation for PET/CT scan, for the evaluation of the oncological disease. The exclusion criteria included: the patient does not want to participate and did not sign the informed consent; the patient has brain neoplasia (primary tumor or brain metastasis); the patient has a blood sugar level over 160 mg/dL even after a correction attempt, represented by the intravenous administration of 500 mL physiological serum.

All imaging protocols were approved by an internal review board. Prior to participation in this study, signed informed consent for PET/CT examination and for data processing was obtained from all participant patients. The study was approved by the Ethical Committee of "Grigore T. Popa" U.M.Ph. Iasi Doctoral School, being part of the doctoral studies of the first author.

After performing an anamnesis specific to the basic pathology of each patient, we performed a standardized cognitive impairment assessment by applying the MMSE test, to evaluate the skills of orientation, attention and calculation, understanding and memory.

Each patient underwent a rigorous and specific preparation for PET/CT examination with an analog glucose radiotracer. Patients with glycemic levels above 160 mg/dL received a 500 mL saline infusion before injecting the radiotracer, normalizing glycemia according to the EANM recommendations for clinical trials (16).

Acquisition of imaging data and reconstruction of images

In the context of pre-existing oncological pathologies evaluation, all patients needed to perform a ^{18}F-FDG PET/CT examination, the acquisition of images including the brain region. The examination was performed using a fully integrated 3D PET/CT Discovery 710 scanner from General Electric and consisted in a full body acquisition CT scout and in two vertex-thigh (10 beds) or vertex-hallux (17 beds) acquisitions, with an acquisition speed of 2 minutes per bed, depending on the existing oncological pathology: one low-dose CT for localization and attenuation correction and another PET.

The dose of radiotracer administered and the uptake period from the time of administration to image acquisition have met the European Association of Nuclear Medicine required standards, the dose ranging from 235 to 592 MBq, with an average of 374.27 ± 55.7MBq, depending on individual body weight, with the uptake period of 44 to 76 minutes, and an average of 55.7 ± 9.5 minutes (3, 15, 16).

The specific processing consisted in the use of basic reconstruction algorithms of OSEM type (ordered-subsets expectation-maximization algorithm) and secondary algorithms of NAC type (non-attenuation correction) and TOF AC type (time-of-flight attenuation correction). The study of images in two dimensions (2D), in three different incidences (axial, coronal and sagittal), as well as in three dimensions (3D, maximum intensity projections or MIP) allowed the analysis of four sets of images per patient (axial, coronal, sagittal and MIP), i.e. the analysis of a total of 120 sets of images.

After specific processing of the acquired images, characteristic regions of interest (ROIs) were identified and plotted on surfaces of 20 mm diameter, both the maximum and the mean standardized uptake values (SUVmax and SUVmean) being subsequently extracted from the following general regions: descending aorta (Ao) corresponding to circulating metabolic activity and bladder or the most intense area of extracerebral glucidic uptake (B), as well as specific regions for functional imaging assessment of dementia: cerebral cortex (CC), cerebellar cortex (Cc), posterior cingulate gyrus (PCG) and precuneus (P). SUVmax and SUVmean values of general and specific ROIs plotted on the two-dimensional images were collected for each patient and statistically analyzed (fig. 1).

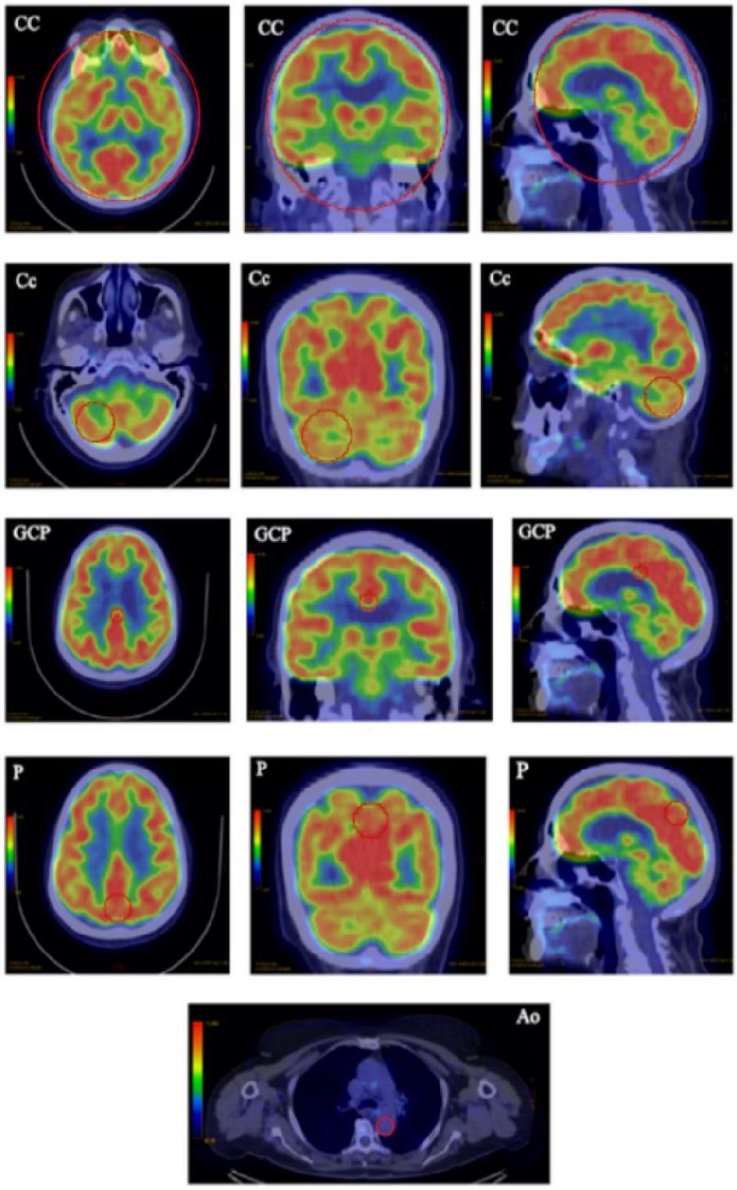

Fig. 1. ^{18}F-FDG PET/CT images axial, coronal and sagittal sections. UV values were collected by delimiting ROIs (dark red circles) in the (CC) Cerebral Cortex, (Cc) Cerebellar cortex, (PCG) Posterior Cingulate Gyrus, (P) Precuneus and (Ao) Descending Aorta

Numerical data analysis

All numerical data used, 17 variables marked V1-V17, are listed in the first table.

Statistical processing included the classical calculation of the following values: mean, minimum, maximum and standard deviation *(SD)*. After that, 4 regression functions are calculated (linear, exponen-

tial, power and logarithmic) for each pair of variables, as described in previous articles (17, 18). The formulas can be seen in the second table**.** For each type of correlation, we calculated *the correlation coefficient (R)* or the ratio between the variable's covariance and the product of their *SDs*

For the variables V1 - V7, V8 or V14, the unique correlation analysis allows the value identification of one variable, knowing only the value of another variable and applying the unique correlation formula.

TABLE I.

List of variables studied for each patient

V1	V2	V3	V4	V5	V6	V7	V8	V9
Age (years old)	MMSE Score	Glycemia (mg/dL)	Administered Dose (MBq)	Uptake Period (minutes)	SUVmaxAo (g/mL)	SUVmaxB (g/mL)	SUVmaxCC (g/mL)	SUVmaxCc (g/mL)

V10	V11	V12	V13	V14	V15	V16	V17
SUVmaxPCG (g/mL)	SUV maxP (g/mL)	SUVRPCG	SUVRP	SUVmeanCC (g/mL)	SUVmeanCc (g/mL)	SUVmeanPCG (g/mL)	SUVmeanP (g/mL)

Age, MMSE Score, Glycemia, Administered Radiopharmaceutical Dose, Uptake Period from injection to examination moment, SUVmax and SUVmean values in (CC) Cerebral Cortex, (Cc) Cerebellar cortex, (PCG) Posterior Cingulate Gyrus, (P) Precuneus, (Ao) Descending Aorta and (B) Bladder, as well as the SUVR for Posterior Cingulate Gyrus represented by SUVRPCG=SUVmaxPCG/SUVmaxCc and for Precuneus represented by SUVRP=SUVmaxP/ SUVmaxCc.

TABLE II.

Variables and correlations calculated

Operation	Formula	Explanations
Linear Correlation	$Y = a \cdot x + b$	x - the independent variable, Y - the calculated variable, a, b – known, constant numbers in the formula, e - the mathematical constant of the exponential ~ 2,71828
Exponential Correlation	$Y = e^{a \cdot x + b}$	
Logarithmic Correlation	$Y = a \cdot ln\, x + b$	
Power Correlation	Y = b · x (weak for all correlations)	
Correlation coefficient (R)	$R = \frac{\sum_{i=1}^{n}(x_i-\overline{x})(y_i-\overline{y})}{\sqrt{\sum_{i=1}^{n}(x_i-\overline{x})^2}\sqrt{\sum_{i=1}^{n}(y_i-\overline{y})^2}}$	$x = x_1, x_2, \ldots x_i, \ldots x_n$ and $y = y_1, y_2, \ldots y_i, \ldots y_n$- the values of the x and y variables, $\overline{x}$ and $\overline{y}$- the averages of the respective variables, R -a number between -1 and 1, indicates the strength of the connection between the two variables (close to 1 -strong bond, 0.5 - average correlation, 0.2 - weak correlation, ≤ 0.1 - lack of correlation).

RESULTS

The 30 studied patients had between 22 and 76 years old, with a balanced male / female ratio of 1.14 (16 men and 14 women). The mean age was 54.03 ± 16.76 SD, divided into age groups: 6 young adults between 20-40 years old, 10 adults between 41-60 years old, 13 middle-old people between 61-75 years old, 1 old man over 76 years old. None of the subjects had an associated cerebral malignant pathology.

The patients group studied had a mean glycemia (V3) of 99.03 mg/dL ± 21.96 SD, with a minimum of 64 mg/dL and a maximum of 179.82 mg/dL.

MMSE tests identified values between 24.4 and 30 and an average of 28.07 ± 1.5DS, all patients examined having a normal cognitive status. The distribution of MMSE evaluation results by age groups is presented in the second figure.

From the acquired imaging data, *$SUVmax_{PCG}$(V10)* had values between 5.1 and 21.3 g/mL, with an average of 13.36 ± 3.77 *SD*, *$SUVmean_{PCG}$(V16)* between 4 and 14 g/mL, an average of 8.68 ± 2.35 *SD*, and *$SUVmax_{P}$(V11)* between 4.8 and 21 g/mL with an average of 13.06 ± 3.81 *SD*, respectively *$SUVmean_{P}$(V17)* between 4.1 and 14.1 g/mL, with an average of 9.93 ± 2.73 *SD*.

The mean, minimum, maximum, and *SD* values for all variables are listed in table III.

Linear, exponential, power and logarithmic regression functions were calculated and the strongest was recorded. As example, for the correlation SUVmeanP–SUVmean PCG (V17-V16) we calculated the 4 regression functions, the strongest being the linear one (R=0.900), where x is the independent variable V16 and Y(x) is the calculated variable V17: Y_((x)) =1.044·x+0.860.

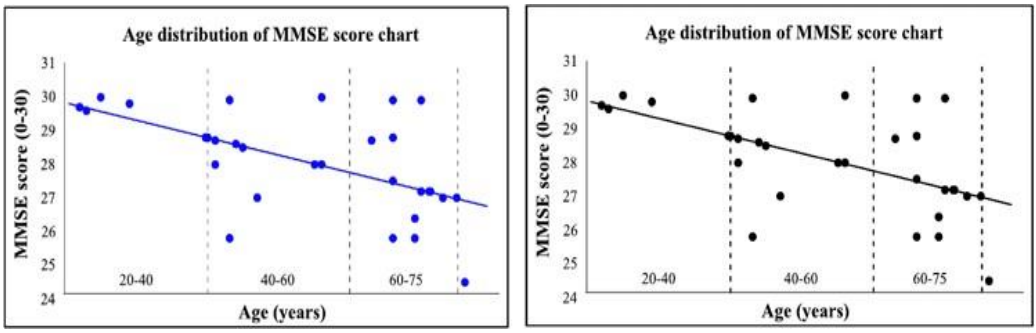

Fig. 2. Age distribution of MMSE score chart.

TABLE III.

Statistical calculation of mean, minimum, maximum and standard deviation values

	V1	V2	V3	V4	V5	V6	V7	V8	V9	V10	V11	V12	V13	V14	V15	V16	V17
Mean	54.03	28.07	99.03	374.3	55.70	2.64	31.98	15.31	11.40	13.36	13.06	1.16	1.13	5.52	7.46	8.68	9.93
SD	16.76	1.50	21.96	72.37	9.51	0.56	22.67	4.49	2.45	3.77	3.81	0.14	0.18	1.44	1.95	2.35	2.73
Min	22.00	24.50	64.0	235.8	44.0	1.90	5.90	6.20	5.60	5.10	4.80	0.91	0.81	2.7	3.8	4.0	4.1
Max	76.00	30.00	179.8	592.2	76.00	4.40	103.9	27.20	16.70	21.30	21.00	1.58	1.54	8.3	12.5	14.0	14.1

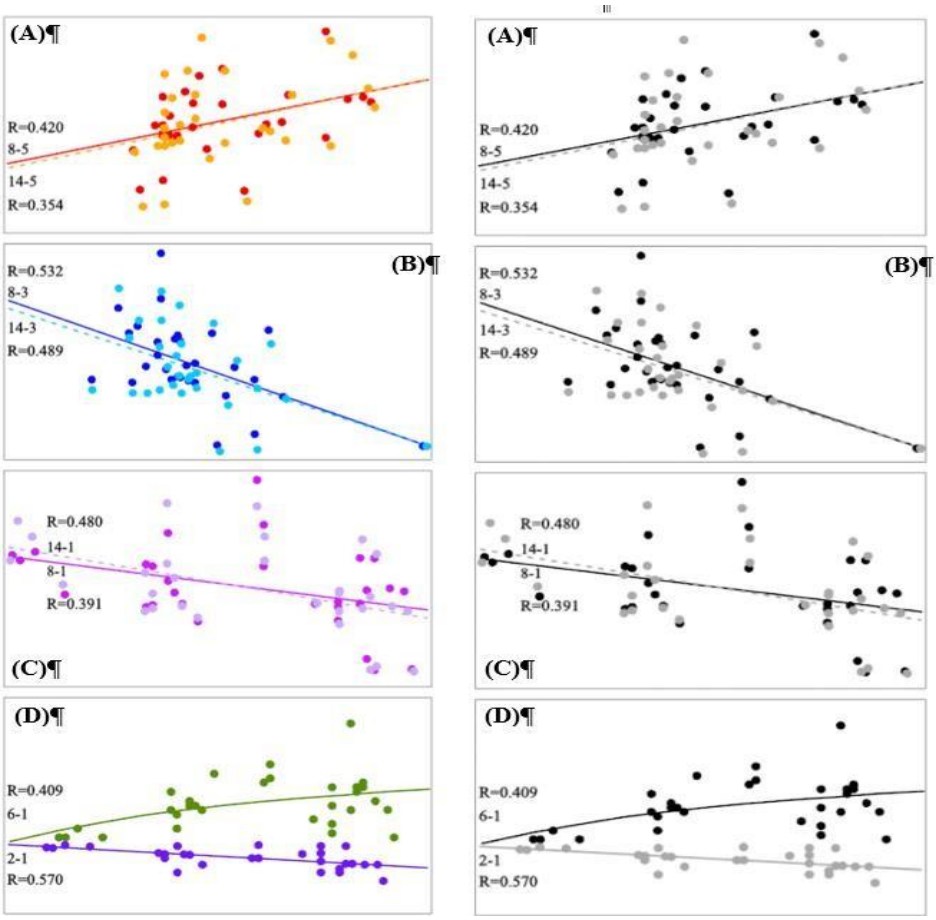

Fig. 3. Significant regression functions (R> 0.350) by unique correlation analysis. Correlations between (A) Uptake Period (5) and SUVmaxCC (8) or SUVmeanCC (14); (B) Glycemia (3) and SUVmaxCC (8) or SUVmeanCC (14); (C) Age (1) and SUVmaxCC (8) or SUVmeanCC (14); (D) Age (1) and MMSE (2) or SUVmaxAo (6)

No correlation was observed between the administered dose and any other variable, the doses being those recommended by international guidelines.

Slightly above average reverse correlations (R>0.5) were found between glycemia and cerebral SUVs, and a slightly higher between glycemia above 120 mg/dL and corresponding SUVs. The same kind of correlation was found between blood glucose and SUVs in specific ROIs SUVmax/meanGCP and SUVmax/meanP, denoting the dependence between brain glucose metabolism and plasma blood glucose.

Using only the function with the highest regression coefficient R, we obtained 34 "strong" correlations (R>0.75), of which 16 "very strong" (R≥0.9), and 3 correlations presenting "assimilable" value slopes (R>0.945).

From these 34 strong and very strong linear and exponential correlations identified between SUVs of the studied ROIs, 7 correlations have "extremely strong" R values (R>0.925) including SUVs of AD cerebral specific ROIs. Four sets of variables have an obvious correlation by the calculation formula of the maximum and average SUVs: SUVmeanP–SUVmaxP (V17-V11), SUVmeanPCG–SUVmaxPCG (V16-V10), SUVmeanCc–SUVmaxCc (V15-V9) and SUVmeanCC–SUVmaxCC (V14-V8). The correlation between SUVmeanP–SUVmaxPCG (V17-V10) is also partially related to the calculation formula. Four other sets: SUVmaxPCG– SUVmaxCC (V10-V8) (R=0.946), SUVmaxP–SUVmaxPCG (V11-V10) (R=0.939), SUVmaxP–SUVmaxCC (V11-V8) (R=0.915), SUVmaxPCG–SU-VmaxCc (V15-V10) (R=0.914) and their SUVmean correspondents are of particular significance, denoting the anatomo-pathological connection between these cerebral regions.

From the unique correlation analysis, we also withhold the average and slightly below average linear correlations (R>0.350) between SUVmaxCC (V8) or SUVmeanCC (V14) and Uptake Period (V5), Glycemia (V3) respective Age (V1). The logarithmic correlation between SUVmaxAo (V6) and Age (V1) and the linear correlation between MMSE score (V2) and Age (V1) have also statistical and medical significance (fig. 3).

Other correlations between the MMSE score and other variables didn't bring relevant information.

Further, the values of the other 16 dependent variables were obtained from the values of the independent variable V8, with regression functions (tab. IV).

Other correlations between different components of MMSE test and other variables did not brought significant data.

Several ^{18}F-FDG PET image analysis methods have been used to predict and detect aMCI conversion to irreversible AD, from qualitative, visual analysis to different quantitative methods: quantitative analysis by traditional and automated methods of deep learning-based algorithms, starting with Minoshima S *et al*. in 1995 (19) until these last years, with the work of De Carli F *et al*. in 2019 based on a Support-Vector Machine (20) or Pan X *et al*. in 2021 with theirs Multi-View Separable Pyramid Network (21). Voxel wise Cox regression based in ^{18}F-FDG PET data for prediction of aMCI conversion to AD was described by Sorensen *et al*. in 2019 (22) and Duan J *et al*. proposed BLADNet in 2023 (23). All these methods, although in different ways, have the same goal as our studies, emphasizing the importance of quantitative image evaluation. Being based also in a regression formula, Sorensen's study is the closest to our try to underline the crucial importance of quantification methods to identify the dementia irreversible starting point by regression analysis.

Our studies of quantitative evaluation of particular cerebral ROIs bring some contribution compared to qualitative evaluation. Our data demonstrated significant correlations between SUVs of specific cerebral ROIs and weak correlations between MMSE score and SUVs in the specific ROIs where modifications appear in different dementias, anatomo-pathological connections between these specific ROIs being undeniable.

The dependence between brain metabolism and glycemic levels shown in our data analysis with slightly above average reverse correlations (R>0.5) is supported by

literature (24). The total cerebral SUV and specific cerebral SUVs are values affected by glycemia, subjects with higher glucose levels presenting lower SUVmax/mean.

TABLE IV.

Single correlation regression functions for the independent variable SUVmaxCC (V8) and its degree of correlation

Weak (& vw.)	$V2(V8) = 0.486 \cdot V8 + 20.651$	$V4(V8) = -200 \cdot V8 + 191.6$	
	$V6(V8) = 0.687 \cdot ln(-9.524 \cdot V8 + 199.657) - 0.060$		$V7(V8) = -4.566 \cdot V8 + 101.826$
Medium	$V1(V8) = -9.524 \cdot V8 + 199.657$	$V3(V8) = -9.174 \cdot V8 + 239.165$	$V5(V8) = 5{,}051 \cdot V8 - 21.576$
Strong correlations	$V9(V8) = 0.505 \cdot V8 + 3.664$	$V10(V8) = 0.796 \cdot V8 + 1.176$	$V11(V8) = 0.755 \cdot V8 + 1.516$
	$V12(V8) = 0.505 \cdot \frac{0.796 \cdot V_8 + 1.176}{V} + 3.6648$	$V13(V8) = 0.505 \cdot \frac{0.755 \cdot V_8 + 1.516}{V} + 3.664$ 8	$V14(V8) = 0.298 \cdot V8 + 0.958$
	$V15(V) = e0.0535 \cdot V8 + 1.1578$	$V16(V8) = 0.479 \cdot V8 + 1.342$	$V17(V8) = 0.522 \cdot V8 + 1.940$

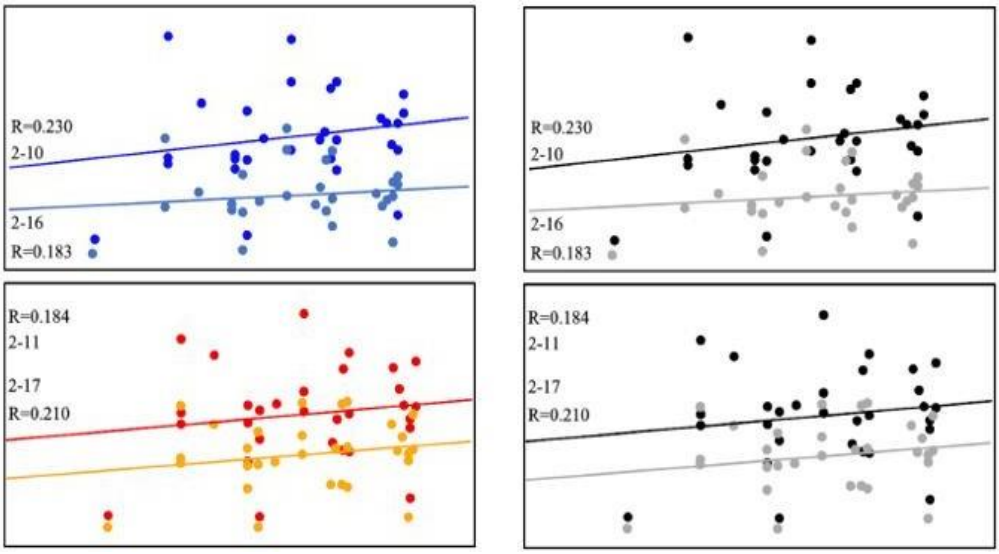

Fig. 4. Correlations between MMSE and AD specific cerebral SUVs

DISCUSSION

We observed that strictly following the protocols recommended by international guidelines, in terms of administered radiopharmaceutical dose, image acquisition protocol, and radiotracer uptake period, patient's blood glucose level before examination, is an essential step (16, 24).

It is also very important to make a judicious choice of the ROIs used for these correlations, allowing future development of some automatic correlations. It is important, also, that the patients do not have brain neoplasia diagnosis. Neurological functions

are not influenced by malignant pathology as long as patients do not have brain neoplasia, including cerebral metastases.

Different correlations between brain areas with important etiopathogenic involvement for AD suggest the usefulness of introducing an index of MCI metabolic visualization in order to identify early dementia. To obtain such an index between specific ROIs requires prospective studies on groups of patients with varying degrees of MCI and AD. Because subjects may perform ^{18}F-FDG PET repeatedly, meantime a MCI process may evolve concomitantly with the malignant pathology, this possibility supporting the usefulness of brain additional quantitative analyzes by introducing such index of MCI status.

Our studies are limited partly by the number of subjects and by the nonspecific pathologies of our patients.

We intend to extend this pilot study to a larger number of patients. Given the neoplasia patients indication for PET-CT images, a limitation of our study could be the uptake period that was established in relation to malignant pathology, also.

Other studies could be developed by improving AD neuroimaging database and by a more complex prospective predictive methodology. A direction would be the elaboration of forecasting software for aMCI to irreversible AD conversion, including multiple dependence correlation formulas with the most powerful connections between variables.

Considering the fact that many patients may be in the borderline period, still socially active, early diagnosis of predementia MCI is useful for limiting economic losses by delaying the onset of AD, thus achieving an MCI and AD precision medicine.

CONCLUSIONS

Even for the identification of a dementia irreversible starting point studies on a greater number of patients are still necessary, our results support the conclusion that the quantitative evaluation of 18F-FDG PET-CT images for cancer patients found in a stage when an MCI can evolve simultaneously would be advisable and could bring useful information for the early onset diagnostic in the precision medicine of the brain process of cognitive loss.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no funding.

RARE COMPLICATION OF RUPTURED ABDOMINAL AORTIC ANEURYSM PRESENTED IN EMERGENCY(Abstract): Aorto-enteric fistula (AEF) is defined as an abnormal communication between the aorta or aortoiliac tree with the gastrointestinal tract and presents as catastrophic gastrointestinal bleeding. The reported annual incidence of primary aorto-enteric fistula is 0.007 per million (only 250 cases reported in literature). Due to the risk of progression to hemorrhagic shock and the high likelihood of surgical intervention, these patients should be closely monitored. **Materials and methods**: This paper includes 35 consecutive patients with ruptured abdominal aortic aneurysm admitted to the Department of Vascular Surgery of the "Sf. Spiridon" County Clinical Emergency Hospital, between 2020 and 2024. **Results:** From the total of 35 patients 3 cases were complicated with primary aorto-digestive fistula (8,57%). 2 of the cases had aorto-duodenal fistula and 1 case had aorto-enteric fistula. **Conclusions:** Complicated abdominal aortic aneurysm with primary aorto-enteric fistula is a rare pathology that requires prompt diagnosis and urgent surgical treatment. **Keywords:** RUPTURED ABDOMINAL AORTIC ANEURYSM, PRIMARY AORTOENTETIC FISTULA.

Aorto-enteric fistula (AEF) is defined as an abnormal communication between the aorta or aortoiliac tree with the gastrointestinal tract and presents as catastrophic gastrointestinal bleeding. The annual incidence is reported to be 0.007 per million and until present only 250 cases were found in literature (1, 2, 3). Primary aorto-duodenal fistula (PADF) is a direct communication between the abdominal aortic aneurysm (AAA) and duodenum and it is an extremely rare cause of upper gastrointestinal bleeding. This condition is often overlooked due to extremely low incidence (4). The most common predisposing conditions for primary aortoenteric fistulas are atherosclerotic abdominal aortic aneurysms or penetrating atherosclerotic ulcers. Less commonly encountered causes include inflammatory or infectious aortitis, diverticulitis, peptic ulcers, appendicitis, diverticulitis, foreign bodies and gastrointestinal malignancies (3, 5, 6, 7). Unlike secondary aortoduodenal fistula (SADF) which occurs

in patients who had previous aortic prosthetic reconstruction, primary aortoduodenal fistula is uncommon (5, 8).

Aortoenteric fistulas can occur with any part of the gastrointestinal tract, the most common location is the transverse portion of the duodenum(D3), which is involved in 60% of cases (3, 9). This is due to its relatively fixed position as compared with the rest of the bowel, and the close relationship of this part of the duodenum to the aorta (3).

The diagnostic is difficult to be recognized only through clinical findings. A classical triad of symptoms was described, including a pulsating, palpable abdominal mass, abdominal pain and gastrointestinal bleeding, but often this pathology is unsuspected until surgery or postmortem (5, 8, 10). In 30% of PADF patients, a brief and self-limiting gastrointestinal bleeding known as a "herald bleed" precedes a subsequent massive hemorrhage (5).

CT scans with contrast are the most reliable modality to evaluate an AAA, with a widely variable sensitivity of 50%-94%, a specificity of 85%-100% and a detection rate of 61% (3, 5, 6). In the appropriate clinical setting, contrast-enhanced CT is reported to have an overall specificity of 100% and a sensitivity of 50% in diagnosing an aortoenteric fistula (3, 11). Though MRI may have similar specificity and sensitivity to CT, the lack of availability in the emergency setting in addition to a longer acquisition time and need for greater technical expertise often limits its use (3).

The unreliability of clinical findings accentuates the need for a high index of suspicion for a PAEF in GI bleeding, especially upper GI bleeds (5). All reports emphasize the need for prompt imagistic investigation in patients presenting with AAA. AEF has high mortality and only prompt intervention can lead to a lifesaving outcome. (12).

Due to the evolution towards hemorrhagic shock and necessity of urgent surgical intervention, these patients should be rapidly diagnosed and admitted in the Vascular Surgery Department. Following surgical treatment patients require advanced intensive care. Prophylactic antibiotics administration is justified in special conditions, as interventions involving the intestinal tract, or the repair of traumatic injuries in contaminated wound (13). Due to the significant morbidity associated with open surgical repair, the use of endovascular repair (EVAR) for the treatment of AAA with AEF can be used as an alternative procedure (14).

MATERIALS AND METHODS

A retrospective study on patients with ruptured AAA admitted in the Vascular Surgery Department St. Spiridon Iasi Hospital between 2020-2024 was conducted. The purpose was to determine the incidence, patient characteristics and evolution in case of AAA associated with AEF.

Over the course of 5 years, a total of 35 patients with a diagnosis of ruptured AAA were admitted and underwent emergency treatment. Presentation symptoms where from discrete to severe: pale skin, diffuse abdominal pain with flank irradiation, tachycardia, tachypnoea, signs of hemorrhagic shock with hypotension, altered consciousness to confusion.

The following data where recorded: demographic characteristics (gender, age, background), perioperative clinical and biological status, presence of aortoduodenal fistula and mortality. All data was statistically analyzed using Microsoft Excel program.

RESULTS

In our study the majority where male patients (80%), the average age was 70 years and 71.42% where from the urban areas. The mortality rate was 74% (fig. 1). Of the total number of patients diagnosed with ruptured AAA through Angio-CT, only 3 cases were complicated with primary aorto-digestive fistula (8.57%) (fig. 2). Two of the cases had aorto-duodenal fistula and 1 case had aorto-enteric fistula. Similar to literature findings, the small number of digestive fistulas identified in our study supports the rarity of this complication.

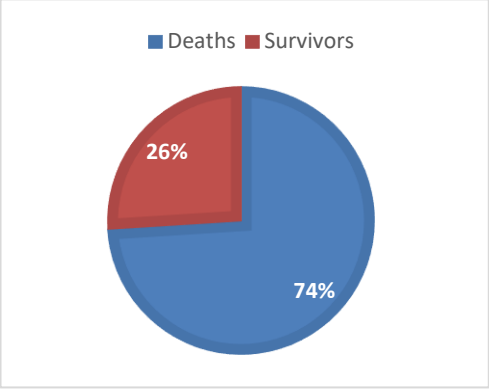

Fig. 1. The mortality rate from the total number of ruptured AAA cases

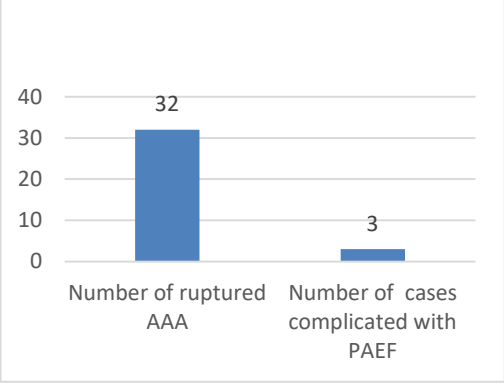

Fig. 2. The incidence of ruptured AAA complicated with PAEF

Regarding the personal pathological history of the patients hospitalized in our clinic with ruptured AAA, there is an increased prevalence of associated cardiovascular pathologies, prevalent essential arterial hypertension (62.85%), chronic heart failure (42.85%), aortic atherosclerosis (17.14%) and embolism and thrombosis of other arteries (31,42%). There is also an increased percentage of metabolic pathologies such as type 2 diabetes complicated with peripheral angiopathy (28.57%), obesity (14.28%), dyslipidemia (11.42%) but also chronic kidney disease and neoplastic pathology, both in the same percentage (14.28%). Considering the study period one risk factor taken in consideration was SARS COV 2 infection (28.57% patients) (tab. I).

TABLE I.

Pathologies associated with AAA in patients from the study group

1. Essential arterial hypertension	62.85%
2. Chronic heart failure	42.85%
3. Embolism and thrombosis of other arteries	31.42%
4. Infection with the SARS COV 2	28.57%
5. Type 2 diabetes complicated with peripheral angiopathy	28.57%
6. Aortic atherosclerosis	17.14%
7. Obesity	14.28%
8. Chronic kidney disease	14.28%
9. Neoplastic pathology	14.28%
10. Dyslipidemia	11.42%

Only 1 in 3 patients presented melenic stools as initial symptom, raising the suspicion of primary AEF.

At the time of admission in the Vascular Surgery Department, 2 of 3 patients had general influenced condition, hemodynamic

instability with need for inotropic support (Noradrenaline) and hemorrhagic shock.

We emphasize on one particular case of a 62-year-old male patient associated generalized abdominal pain with lumbar irradiation, bilateral lower limb paresthesia and melenic stools. The patient was hemodynamically stable which is why he underwent gastric endoscopy without revealing the source of bleeding. The Angio-CT exam showed a chronic partial thrombosed sacciform infrarenal AAA, with extended parietal hematoma on the right primitive iliac artery and raises the suspicion of a duodenal lesion by the contiguity of the aneurysm (fig. 3).

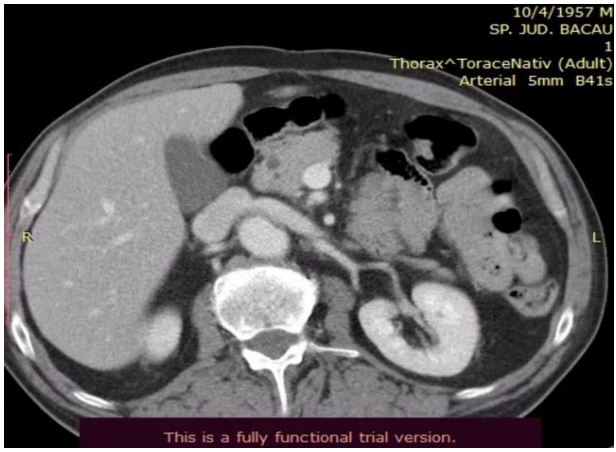

Fig. 3. Angio-CT image of ruptured AAA complicated with ADF

The patient underwent emergency surgery. The procedure included the following stages: infrarenal AAA aneurysmectomy, aorto-duodenal fistula closure, duodenorrhaphy, epiploonoplasty, left aorto-iliac bypass (left common iliac artery) and right aorto-femoral bypass (right common femoral artery) with synthetic Dacron graft (fig. 4).

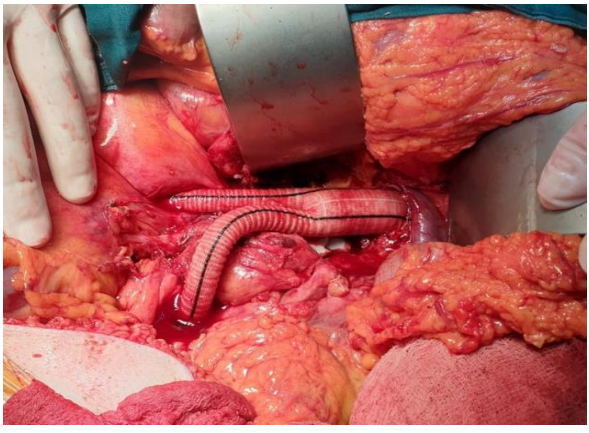

Fig. 4. Intraoperative aspect: left aorto-iliac bypass (left common iliac artery) and right aorto-femoral bypass (right common femoral artery) with synthetic Dacron graft.

Postoperative the patient was admitted in the intensive care. The evolution was favorable. Patients graft patency was initial certified by the presence of pulses in the bilateral distal arteries. The patient was discharged surgically cured. A follow-up included clinical and angio-CT evaluation.

After two years, the patient returns to the emergency department for diffuse abdominal pain and melenical stools, with SAEF observation. Immediate surgical intervention was required and it consisted in exploratory laparotomy, longitudinal duodenotomy, posterior endoluminal suture of D3, duodenorrhaphy, epiploonoplasty. The unfavorable evolution despite multiple surgical reinterventions led to the death of the patient at about1 month from admission.

DISCUSSION

Similar to literature findings, our study revealed a low prevalence of primary AEF as a complication of ruptured AAA. Given this aspect, nonspecific symptoms and rare gastrointestinal bleeding, it is hard to suspect this pathology.

The low prevalence of primary AEF can be attributed to several facts. Ruptured AAA incidence decreased due to screening and surgical or endovascular treatment prior to rupture. Also, AAA have higher success rate when treated electively (15). As we find in the literature, there is a high difference in mortality between patients who are surgically treated electively and those who benefit from emergency surgical treatment. Prevalence of abdominal aortic aneurysm in men older than age 65 has been decreasing over time, falling from about 4-8% to 2% in recent studies (15). The incidence of rupture was demonstrated to decrease as a result of active screening, increased surveillance and intervention in noncomplicated AAA.

The average age of presentation cited in the literature for patients with AAA is 63-64 years. The fact that the patients from our group are older can be attributed to the lack of screening programs leading to a later diagnostic. Similar to data in the literature AAA is being more frequent identified in men (same percentage - 80%) (6, 16, 17).

As mentioned, the clinical presentation of primary AEF is non-specific, consisting in digestive bleeding and abdominal or lumbar pain. The complete classic triad associating a palpable abdominal mass is found in only 11% of patients with AEF (3, 5, 6, 16, 18).

All patients underwent contrast CT scans for diagnosis and management planning. This imagistic investigation remains the study of choice with the highest detection rate. Imaging features suggestive of PAEF include air within the aortic wall, focal bowel wall thickening, disruption of pre-aortic fat, or the pathognomonic sign of contrast in proximity or in the small bowel (5, 6).

A review of the literature (366 cases) showed that 72.9% of PAEFs were in the duodenum, with 66% in the third portion of the duodenum and 33% in the fourth portion (D4) (19). Georgeades *et al.* shows in their study that 16 of the cases were in D3, 6 were in D4, 1 was in D2, and 13 cases had PADFs in an unspecified duodenal location (6).

When considering management of PADF, there are three main objectives - hemorrhage control, contamination / infection control, and maintenance of distal perfusion. Surgery remains the primary treatment modality of ADFs, with a periop-

erative mortality rate of 50% or higher with survival rates between 18% and 93% (6). Direct closure of the duodenal fistula appears to be the most common, but other procedures include resection with anastomosis, pyloric or duodenal exclusion, pancreatico-duodenectomy, Bilroth type I or II reconstruction, Roux-en-Y reconstruction, and others (6, 17, 18, 20-25).

Surgical technique has also been improving over time. In 2016 Ho S *et al.* reported mortality associated with PAEF repair of 34% compared with 44% prior to 1994 (5).

One important aspect of surgical repair is the use of an omental interposition flap between the aorta and duodenum. One study evaluated outcomes of ADF repair in 791 cases and noted that an omental interposition was the strongest predictor of survival. The most common cause of death is fistula recurrence, which occurs in 41.8% of patients, and has a higher frequency in those that did not have an omental interposition (6, 17).

Another important aspect in the subsequent evolution of the patients is the general condition at the time of presentation, being directly correlated with evolution. All 3 cases of ruptured AAA with primary FAE benefited from emergency surgery, regardless of clinical-biological status. Good general status and hemodynamically stable are correlated with postoperative favorably evolution.

CONCLUSIONS

Complicated AAA with primary FAE is a rare pathology that requires an increased degree of susceptibility to facilitate prompt diagnosis and initiation of specialized surgical treatment. This pathology is also associated with an increased mortality rate despite multidisciplinary treatment. Beside prompt surgical treatment and postoperative advanced intensive care, patient evolution is highly influenced by the general condition and preoperative clinical and biological parameters.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

KRUKENBERG TUMOR MIMICKING OVARIAN MASS (Abstract): Krukenberg disease is part of metastatic malignancies with the primary tumor usually located in the stomach, but any part of the gastrointestinal tract may be involved, including the small or large intestine. **Materials and methods:** We used statistical analysis to evaluate the link between risk factors and prognosis in 36 patients, over an 8-year period, i.e. between 2016 and 2024. **Results:** We examined the cases with ovarian metastasis due to gastrointestinal tumor over a ten-year period and found that this tumor made up 1% of the total ovarian cancers that required surgery in our department, these statistical findings being in line with literature data. **Discussion:** Managing this disease can be very difficult because of its poor prognosis. The patients have obviously a hard time understanding the pathway and the need for further investigations that include endoscopy, PET-MRI and second surgery programming, in order to improve their survival rate. **Conclusions:** An aggressive treatment is considered the key to prolong the patient's life, and the best management of this disease is to make as many studies as possible in this direction, in order to better understand and apply the interdisciplinary means of investigations and treatments. **Keywords:** KRUKENBERG TUMOR, OVARIES, ABDOMINAL PAIN.

INTRODUCTION

Krukenberg disease is part of metastatic malignancies with usually late-stage localizations in the ovary, associating a type of adenocarcinoma from the gastrointestinal tract, with cells rich in mucus and a typical ring sign presentation. In the late stages, the localization generally involves

both ovaries (in more than 80% of the cases). It was first mentioned more than 120 years ago. The starting point is usually the stomach, but any part of the gastrointestinal tract can be involved, such as the colorectal area, the appendix or the pancreas and literature shows that even the breast and the cervix can be affected. The main symptoms experienced by patients include an enlarged abdomen over a short time, flatulence, loss of appetite, weight loss, and there were reported cases where it occurred simultaneously with a pregnancy. The disease dissemination includes lymphatic and hematogenous routes, with the first one being more likely. Microscopically, it shows a first infiltration with tumoral cells on the cortex surface of the ovary, with a high number of positive lymph nodes (1, 2). The differential diagnosis is difficult to set in cases with unknown primary site, because ovarian mucinous tumors can mimic well signet-ring type cells. CA 125 is unspecific in Krukenberg cases, but may have a modest increase, up to 40 u/mL (3).

The primary development localization of the tumor is often the stomach or a colorectal cancer, in more than 70-90% of the cases. There are also other rare sites, such as the gallbladder. The appendix, breast, small intestine, pancreas or urinary bladder could also be affected. The median age at diagnosis is 40 years. The incidence rate in high risk areas with gastric cancer, such as Asia, can be up to 20% of the ovarian cancers. Pathophysiological, we describe three pathways of dissemination, such as: the lymphatic system, the hematogenous route and the trans coelomic dissemination, less recognized due to the poor infiltrates from the peritoneum, when laparotomy is performed (4-6).

The anatomopathological examination usually describes bilateral ovarian enlargement, with irregular and lumpy-looking surface. The tumors have a solid consistency, may have adhesions or near implants and could initially be considered primary cancers. Microscopy reveals a typical mucin laden sign-ring cell aspect of the tumoral cells. If this is absent, two other descriptions should be included, such as the stromal implication of the tumoral characteristics, or the sarcomatous proliferation of the ovarian stroma. Immunohistochemistry shows positive staining for cytokeratin, which is also called pan cytokeratin AE1-AE3, and positive staining for the membrane epithelial antigens (EMA). Vimentin and inhibin immunohistochemistry are negative. The most frequent cytokeratin's are 7 and 20 (7). A presurgical staging is important in describing a possible Krukenberg disease. The markers, such as CA-125, may be high and are important after the surgery, in appreciating a possible relapse.

The differential diagnosis is set after immunohistochemistry and involves other malignant ovarian tumors, but these typical markers offer a more accurate diagnosis. The prognosis is poor, less than 2 years of survival, but many efforts are made to have minimal microscopic disease dissemination during surgery. The Krukenberg disease is part of a severe oncological disease with multiorgan involvement that occurs as the final stage of a gastrointestinal primary tumor. When diagnosed, the disease has usually spread to both ovaries in more than 80% of the cases.

Our aim was to draw attention to this gastrointestinal disease that is often diagnosed during a laparotomy with an extemporaneous examination by gynecological surgeons. Before the surgery, it is important to provide an accurate anamnesis and, in cases of suspicions, to further recommend digestive endoscopic evaluation.

MATERIALS AND METHODS

We used statistical analysis to evaluate the link between risk factors and prognosis in 36 female patients, with ovarian metastasis due to gastrointestinal tumor, over an 8-year period, i.e. between 2016 and 2024, in a tertiary maternity center from Iași, Romania.

Patients total hospitalization time in our hospital ranged from 9 days to 21 days, including post-surgery hospitalization. In most cases, the diagnosis was suspected immediately intraoperatively and required extemporaneous examination. Surgery consisted of total hysterectomy with bilateral adnexectomy in 100% of the cases. Adhesiolysis was performed in 25% of the cases, and multiple biopsies of the peritoneum and great omentum were performed. In 25% of the cases, ascites was present and a cytological diagnosis was required. The extragenital macroscopic masses were localized on either the colon or the rectum and were found in 25% of the cases. During hospitalization, a gastroscopy and colonoscopy were performed postoperatively to identify the primary tumor, that was found in 25% of the cases during our hospitalization.

RESULTS

We found that this ovarian tumor made up 1% of the total ovarian cancers that required surgery in our department, these statistical findings being in line with literature data. All 36 female patients were aged between 38 and 64 and they had total hysterectomy with bilateral adnexectomy, in all cases.

The anatomopathological specimens revealed bilateral ovarian tumors in 100% of the cases. The size of the ovaries ranged from 4.5 cm to 10 cm. In all our cases, microscopy revealed cohesive tumor cells, arranged in islets, delimited by fine bands of stroma, solid areas and areas with tubular cribriform architecture. Other aspects included tumor cells with marked nuclear pleomorphism, atypical mitoses, tumor cells in signet ring and large areas of tumor necrosis. In 25% of the cases, the uterine serosa showed tumor implants, while in 25% of the cases the uterus had the same ovarian histological appearance of diffuse gastric adenocarcinoma with “signet ring” in the form of tubulo-glandular areas in mucoid or edematous stroma, with vascular lymphatic invasion. Uterine metastases involve the cervical and endometrial stroma, myometrium, and uterine wall, with frequent images of lymphatic invasion in 25% of the cases. Invasion of the parietal peritoneum or omentum with tumor implants was identified at biopsy in 25% of the cases. All the anatomopathological specimens examined showed loosely cohesive tumor cells, arranged in islets, delimited by fine bands of stroma, solid areas and areas with tubular, cribriform architecture (tab. I).

Tumor cells with marked nuclear pleomorphism, atypical mitoses, tumor cells in “signet ring” and extensive areas of tumor necrosis. In 25% of the cases, the uterine serosa showed tumor implants, and in 25% of the cases the uterus had the same ovarian histological appearance of diffuse gastric adenocarcinoma with “signet ring” in the form of tubulo-glandular areas in mucoid or edematous stroma, with vascular lymphatic invasion. Uterine metastases in the uterus involved the cervical and endometrial stroma, myometrium, and uterine walls, with frequent images of lymphatic invasion in 25% of the cases. Invasion of the parietal peritoneum or omentum with tumor implants was identified at biopsy in 25% of the cases (tab. II).

TABLE I.

Anatomopathological findings correlation with disease severity

Ovary and fallopian tube, uterus appearance	Ovary and fallopian tube, uterus appearance	Peritoneum
Macroscopic appearance	**Microscopic appearance**	**Associated histopathological appearance**
Ovarian mean dimensions 9± 2 cm (97.2%)	Ovarian metastases fallopian tube metastases uterine metastases in the uterine serosa, cervical and endometrial stroma	Peritoneal carcinomatosis
Lumpy outer surface, solid appearance in section, yellowish color, firm consistency (97.2%)	Diffuse gastric adenocarcinoma cells predominantly from "signet ring cells" arranged as pools, nests and isolated	Rectal invasion
Uterine wall with thin serosa, uterine mucosa thickened up to 3 cm, in 9 cases uterine invasion is found - in the uterine serosa, tumor implants, or in the endometrium (14.4%)	Tubulo-glandular areas included in mucoid or edematous stroma	Uterine sacral ligaments infiltration
Without intraoperative primary tumor identification (86 %)	Images of vasculo-lymphatic invasion	Bladder implants

TABLE II.

Clinical characteristics of ovarian disease progression and risk factors

Clinical characteristics	Krukenberg tumor group n=36
Age, years (mean ± SD)	50 ±4.31
Parity	Multiparous 24 (86 %)
Menopause	Premenopausal 9 (3.24%) Menopause 27 (97.2%)
Previous gynecological surgery	Uterine fibroma 4 (14.4%)
History of ovarian tumor	Previous benign ovarian cyst 5 (18%)
Important comorbidities - cardiac insufficiency, pelvic adhesions, ascites	Ascites 27 (97.2%) Cardiac insufficiency 4 (14.4%) Adhesions 27 (97.2%)

DISCUSSION

Worldwide, ovarian cancer is in the top seven oncological pathologies in women and represents the eighth cause of mortality in female patients (8, 9).

Most malignant forms that affect the ovary are the epithelial carcinoma, the germ cell tumor carcinoma, the sex cord-stromal tumor, and metastasis, like Krukenberg's tumor. The detection of the last one, this particular type of late ovarian cancer, was difficult, as there is no screening program for its early detection. The best-known cancer types that give metastasis in the ovaries are the breast, colorectal, gastric, and appendix tumors. Pregnancy and metastasis may occur simultaneously. The bilateral involvement of the ovaries is frequent at this stage (10-12).

The Krukenberg tumor from pulmonary malignancy is rare. The immunohistochemical examination of the pleural or ascites

fluid cytology can confirm the diagnosis of the main organ origin (13-17). When considering breast cancer primary tumor and metastasis to the ovary, most of the metastatic breast carcinomas are found to be positive for estrogen receptor on immunohistochemistry (17-19). Studies show that most of the gastric tumors are positive for CDX2 and only a few are positive for SATB2 markers. The colorectal and appendiceal cancers are positive for CDX2 and SATB2. GATA3 stains are positive in almost all breast primaries and in more than half of the bladder cancers. Almost all the pulmonary cancers are positive for TTF1. PAX8 is negative in gastric, colorectal and appendiceal cancers.

The management of this disease can be very difficult because of its poor prognosis. The patients obviously have a hard time understanding the pathway and the need for further investigations that include endoscopy, PET-MRI scan and a second surgery, in order to improve their survival rate. Aggressive surgery, designed to reduce the macroscopic disease and limit the number of cancerous cells, is recommended. When only one ovary is affected, bilateral oophorectomy is performed in order to decrease the risk of further dissemination. After the surgery, none of the results are considered microscopically negative, unless we perform the resection with negative margins and if a little tone or a big mass is still found in the pelvis after the operation. The differential diagnosis is difficult to set in cases with unknown primary site, because the ovarian mucinous tumors can mimic well “signet-ring” type cells. CA 125 is unspecific in Krukenberg cases, but may have a modest increase, up to 40 u/ml (19). A metastatic tumor can often be the first manifestation of a neoplastic disease. A significant number of CK7(+)/CK20(-) patients were found to have gastric cancer. The most cited and used tumor markers in the immunohistochemical diagnosis of metastatic ovarian tumors are cytokeratins: CK20 and CK7(20-24). The incidence rate of multiple primary cancers among malignancies can be up to 8%. Different immunological markers have been cited for ovarian cancers, such as PAX8 and WT1, but etiopathological pathways have yet to be surely discovered (25).

When discussing the various pathways of the spread of Krukenberg tumor, there are various theories such as: retrograde lymphatic dissemination, the main pathway of dissemination in gastric cancer metastases, hematogenous pathway spread most frequently encountered in colorectal cancer, and trans peritoneal direct spread in peritoneal carcinomatosis. Prognostic factors influence the spreading of any disease, according to parameters and factors in Krukenberg tumors disease that include peritoneal involvement, synchronous presentation, ascites, and increased serum carcinoembryonic antigen levels.

There are no apparent differences between the symptoms arising from primary and secondary ovarian malignancies. Krukenberg tumors remain asymptomatic until very advanced stages, therefore any sign of abdomen enlargement or ascites should be considered for further follow up. Although Krukenberg tumors may be induced by complex mechanisms, lymph node metastasis is considered to be the most significant risk factor for recurrence. Various articles compare patients with advanced Krukenberg tumor at a young age and establish that a functioning young ovary is prone to metastatic disease due to the rich ovarian blood supply predisposing to hematogenous metastasis.

We mostly promote early symptoms presentation, annual check-up and to encourage multidisciplinary approach when

patient symptoms are not correctly addressed and resolved.

We performed a statistical literature data review since 2021, where more than 3000 patients had the pylorus sphincter as main localization, 42.5% of the cases, and the second localization involved the colon in 26.1% of the cases. Ovarian cancers with idiopathic localization were encountered in 12.2% of the cases, while the urinary tract and bladder were found in less than 1% of the cases (25, 26).

The data reviewed involved the examination of the efficacy of surgery in patients with gastric cancer and synchronous ovarian metastases. The patients underwent resection of ovarian metastases, either alone or in conjunction with gastric resection and lymph node dissection. The newest data show the efficiency of systemic and/or hyperthermic intraperitoneal chemotherapy (HIPEC) after surgery. Median overall survival was significantly greater in those patients who underwent excision before systemic chemotherapy compared to those who underwent simultaneous gastrectomy and metastasectomy following chemotherapy. The use of HIPEC improved overall survival in patients with peritoneal metastases.

In a smaller statistical group, involving 128 patients, in the early 2000, over a 20-year period, the median age at diagnosis of the disease was 48 years, with a mean average survival rate of 16 months after the diagnosis. Data show that synchronous metastasis ($p=0.0080$), pelvic invasion ($p=0.0138$) and ascites are the main unfavorable factors (27).

CONCLUSIONS

The screening of patients with gastrointestinal symptoms is important and full abdominal ultrasound scan is recommended in order to evaluate the pelvis for metastatic diseases.

The survival rate increases if the diagnosis is set with unilateral disease. Chemotherapy can improve the quality of life of these patients and aggressive surgery is recommended in order to obtain macroscopically free lesion disease. This article is important for the need to address further investigations in cases of undetected tumor sites, in order to better perform multidisciplinary second surgeries, together with the oncological surgeon and the oncological multidisciplinary team's implication.

Ovarian metastases are present in up to 10% of the women with inoperable gastrointestinal cancer, and studies have shown that the patients' age is constantly decreasing. Therefore, early diagnosis is mandatory for the improvement of the survival rates and the patient's life quality.

ASSOCIATION BETWEEN ALCOHOL-RELATED LIVER CIRRHOSIS AND LATE STAGES AT DIAGNOSIS OF HEPATOCELLULAR CARCINOMA (Abstract): Hepatocellular carcinoma (HCC) is a major complication of liver cirrhosis (LC), and its prognosis is highly dependent on the stage at diagnosis. Alcohol-related liver disease (ALD) is an increasing cause of cirrhosis worldwide, but its impact on the stage of HCC diagnosis remains unclear. **Aim** of the study: to evaluate the stage at which HCC is diagnosed and assess whether alcohol-related cirrhosis predisposes patients to a more advanced-stage presentation. **Materials and methods:** We conducted a retrospective observational study of 152 patients diagnosed with HCC at a tertiary center between January 2022 and December 2023. Patients were classified by cirrhosis etiology (alcohol-related vs. viral hepatitis-related) and categorized by HCC stage at diagnosis according to the 2022 Barcelona Clinic Liver Cancer (BCLC) classification. For analysis, patients were grouped based on curative treatment eligibility: curative stages (BCLC 0-A and selected B1 cases) and non-curative stages (BCLC B2-B3, C, and D). **Results:** Among the 152 patients analyzed, 54 (35.5%) had alcohol-related cirrhosis, and 96 (63.2%) had viral hepatitis-related cirrhosis. At diagnosis, no patients were identified at the very early stage (BCLC 0), while 18.4% were diagnosed at a curative stage and 81.6% at a non-curative stage. Notably, nearly half of all patients (46%) presented at the terminal stage (BCLC D). The proportion of patients diagnosed at a curative stage was significantly lower in those with alcohol-related cirrhosis (7.4%) compared to those with viral hepatitis-related cirrhosis (24%) ($p = 0.01$). Multivariate analysis confirmed that alcohol-related cirrhosis was independently associated with a higher likelihood of non-curative stage diagnosis. **Conclusions**: Patients with alcohol-related cirrhosis are significantly more likely to be diagnosed with HCC at a non-curative stage compared to those with viral hepatitis-related cirrhosis. This disparity underscores the need for improved HCC surveillance strategies in this high-risk population, including better patient engagement, integration of hepatology with addiction services, and enhanced screening adherence programs. Addressing these challenges could facilitate earlier diagnosis and improve treatment opportunities for patients with alcohol-related cirrhosis. **Keywords:** ALCOHOL-RELATED LIVER DISEASE, CIRRHOSIS, HEPATOCELLULAR CARCINOMA, STAGING, CURATIVE TREATMENT.

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common primary liver malignancy and represents a major global health burden. It is one of the most serious long-term complications of liver cirrhosis (LC), with most cases developing in patients with underlying cirrhotic disease (1). The prognosis of HCC is highly dependent on the stage at the time of diagnosis, as early-stage detection allows for potentially curative treatments such as liver transplantation, surgical resection, or locoregional therapies (2). In contrast, advanced-stage HCC is associated with limited therapeutic options and poor survival outcomes.

The development of HCC is strongly linked to various etiological factors that contribute to chronic liver disease and cirrhosis, including viral hepatitis - hepatitis B virus (HBV) with or without hepatitis D virus (HDV), and hepatitis C virus (HCV), metabolic dysfunction-associated steatotic liver disease (MASLD, formerly non-alcoholic fatty liver disease - NAFLD), and alcohol-related liver disease (ALD) (3,4). Among these, ALD remains a significant and growing cause of cirrhosis and HCC worldwide (5). However, the impact of cirrhosis etiology on the stage at which HCC is diagnosed is not fully understood.

Alcohol-related cirrhosis is associated with multiple clinical and socioeconomic factors that may contribute to delayed diagnosis, including the absence of routine surveillance, more frequent decompensation events that mask tumor-related symptoms, and differences in healthcare-seeking behavior (6). Understanding whether ALD-related cirrhosis predisposes patients to a later-stage diagnosis of HCC is critical for improving surveillance strategies and optimizing patient outcomes.

The **aim** of this study is to assess the stage at which HCC is diagnosed and to determine whether cirrhosis etiology, particularly alcohol-related cirrhosis, influences the likelihood of an advanced-stage presentation at the time of diagnosis.

MATERIAL AND METHODS

Patients. We conducted a retrospective observational study of patients diagnosed with hepatocellular carcinoma (HCC) at a tertiary reference center over a two-year period (January 2022 – December 2023). Eligible patients were identified from the hospital's electronic medical records and included if they had a confirmed diagnosis of HCC based on imaging criteria (contrast-enhanced computed tomography or magnetic resonance imaging) and/or histopathological confirmation.

Methods. We collected demographic data, including age, sex, and relevant clinical history. The etiology of liver cirrhosis was recorded for each patient and classified as alcohol-related cirrhosis, viral hepatitis (HBV with or without HDV, and HCV), MASLD, or other less common causes (including autoimmune etiology, hereditary hemochromatosis, Wilson's disease, and other rare etiologies).

The stage of HCC at the time of diagnosis was determined using the 2022 Barcelona Clinic Liver Cancer (BCLC) classification system (7). This system classifies patients into five stages (one of them comprising three substages) based on tumor burden, liver function, and performance status (Table I).

For this study, patients were categorized into two groups based on the feasibility of curative treatment: those with ***curative stages at diagnosis***, defined as BCLC 0-A and selected BCLC B1 cases eligible for liver transplantation, and those with ***non-***

curative stages at diagnosis, comprising BCLC B2-B3, C, and D.

This study was conducted in accordance with the principles of the Declaration of Helsinki and was approved by the institutional ethics committee. Informed consent was waived due to the retrospective nature of the study.

TABLE I.
BCLC staging (7)

BCLC Stage	Characterization
0 (Very Early Stage)	Single, small tumors without vascular invasion and good liver function, suitable for curative treatment (e.g., surgical resection or ablation)
A (Early Stage):	Single or multiple tumors with good liver function, candidates for curative treatment (e.g., resection, liver transplantation, or ablation)
B1 (Intermediate Stage, Subgroup 1)	Multiple tumors with a low tumor burden and good liver function, potentially eligible for liver transplantation
B2 (Intermediate Stage, Subgroup 2)	Multiple tumors with a higher tumor burden, but with preserved liver function and no signs of advanced liver disease
B3 (Intermediate Stage, Subgroup 3)	Multiple tumors associated with moderate hepatic dysfunction (e.g., ascites or varices), without signs of advanced liver failure
C (Advanced Stage)	Large or multinodular tumors with vascular invasion, or extrahepatic spread, with poor liver function, typically treated with systemic therapies
D (End-Stage)	Extensive tumor burden with decompensated liver disease, managed with palliative care

Statistical analysis was performed using the *SPSS version 17.0 software* (SPSS Inc., Chicago, IL, USA). Descriptive statistics were used to summarize patient characteristics. Comparisons between groups were made using the chi-square test. A p-value of <0.05 was considered statistically significant.

RESULTS

Patients' characteristics

A total of 152 patients with hepatocellular carcinoma (HCC) were analyzed (Table II). Among them, 54 patients (35.53%) had alcohol-related liver cirrhosis (LC), while 96 patients (63.16%) had a viral etiology: 30 with hepatitis B virus (HBV), 6 with both HBV and hepatitis C virus (HCV), 8 with both HBV and hepatitis D virus (HDV), and 52 with hepatitis C virus (HCV) alone. Additionally, one patient (0.66%) had metabolic dysfunction-associated steatotic liver disease (MASLD), and one (0.66%) had autoimmune-related cirrhosis.

HCC staging

According to the BCLC classification, 10 patients were diagnosed at the early stage (A), 33 at the intermediate stage (B) (5 in B1, 11 in B2, and 17 in B3), 39 at the advanced stage (C), and 70 at the terminal stage (D). Notably, no cases were detected at a very early stage (BCLC 0).

Curative treatment eligibility

When grouped by treatment eligibility, 28 patients (18.4%) were diagnosed at a curative stage (BCLC A or selected B1 cases eligible for liver transplantation), while 124 (81.6%) were diagnosed at a non-curative stage (BCLC B2-B3, C, or D). This distribution highlights a significant predominance of late (especially advanced-stage and end-stage diagnosis), limiting therapeutic options for most patients.

TABLE II.

Patients' clinical characteristics, cirrhosis etiology and stage at diagnosis

Characteristics	Total number of patients = 152
Age (years), mean +/- SD	65 +/- 10
Range (years)	44-86
Sex, male, n (%)	96 (63.2%)
Etiology of cirrhosis, n (%)	
- Alcohol-related	54 (35.53%)
- HBV	30 (19.74%)
- HBV+HCV	6 (3.95%)
- HBV+HDV	8 (5.26%)
- HCV	52 (34.21%)
- MASLD	1 (0.66%)
- Autoimmune	1 (0.66%)
Diagnostic stage, n (%)	
- Curative	28 (18.4%)
- Non-curative	124 (81.6%)

Staging by etiology

We subsequently analyzed patients based on etiology, comparing those with alcohol-related cirrhosis to those with viral hepatitis-related cirrhosis (tab. III). Due to the small numbers, we excluded the two patients with other etiologies (one with autoimmune cirrhosis and one with MASLD). Among patients with alcohol-related cirrhosis, only 4 (7.4%) were diagnosed at a curative stage, while 50 (92.6%) were diagnosed at a non-curative stage. In contrast, among patients with viral hepatitis-related cirrhosis, 23 were diagnosed at a curative stage (24%), while 73 (76%) were diagnosed at a non-curative stage. Comparative analysis using the chi-square method revealed that the proportion of patients diagnosed at a curative stage was significantly lower among those with alcohol-related cirrhosis compared to those with viral hepatitis-related cirrhosis ($p = 0.01$). This finding underscores the challenges faced by patients with alcohol-related cirrhosis in accessing timely and effective treatment options.

TABLE III.

Stage at diagnosis according to cirrhosis etiology

	Alcohol-related cirrhosis (n=54)	Viral hepatitis-related cirrhosis (n=96)	p-value
BCLC stage, n (%)			
Potentially curable stages	**4 (7.4%)**	**23 (24%)**	
0 (very early)	0	0	
A (early)	2 (3.7%)	8 (8.3%)	
B1 (intermediate 1)	2 (3.7%)	15 (15.6%)	
Stages not eligible for curative treatment	**50 (92.6%)**	**73 (76%)**	p = 0.01
	4 (7.4%)	7 (7.3%)	
B2 (intermediate 2)	2 (3.7%)	3 (3.1%)	
B3 (intermediate 3)	18 (33.3%)	19 (19.8%)	
C (advanced)	26 (48.2%)	44 (45.8%)	
D (terminal)			

DISCUSSION

A striking finding of our study is the exceptionally high proportion of patients diagnosed at non-curative stages (81.6%), with no cases identified in the very early stage and only 18.4% diagnosed at curative stages, highlighting a critical gap in early detection and intervention.

Moreover, nearly half of the patients in both alcohol-related and viral cirrhosis groups were diagnosed at the terminal stage (BCLC D). According to the current staging system, patients with severely impaired liver function are automatically classified as Stage D, regardless of tumor burden (7). This could be seen as a limitation of the actual staging system, because this means that even patients with small, potentially treatable tumors may be excluded from curative or life-prolonging interventions, because of end-stage liver disease. Nevertheless, while this classification reflects the poor overall prognosis in such cases, it also raises concerns about missed therapeutic opportunities, particularly in centers where liver transplantation is accessible. Given the evolving landscape of HCC management, with improvements in locoregional therapies and transplant eligibility criteria, a more nuanced approach that considers individual patient profiles-beyond hepatic function alone-could be beneficial in refining treatment decisions.

At the same time, most hospitalized patients fall into this D category, while very few have preserved liver function-these patients may be evaluated in outpatient settings and possibly managed directly by surgery, oncology, or interventional radiology without requiring admission to the gastroenterology department. This could partly explain the exceptionally high proportion of patients diagnosed at Stage D.

Our study demonstrates that patients with hepatocellular carcinoma (HCC) who have alcohol-related cirrhosis are significantly more frequently diagnosed at non-curative stages compared to those with viral hepatitis-related cirrhosis. This finding highlights critical disparities in disease surveillance, healthcare engagement, and modifiable risk factors between these two groups.

One of the most plausible explanations for this discrepancy is the reduced adherence of patients with alcohol-related liver disease to regular medical follow-up and surveillance programs. Chronic alcohol consumption is often associated with poor healthcare-seeking behavior, lower compliance with medical recommendations, and social or psychological factors that further hinder early diagnosis. Unlike patients with viral hepatitis, who are often identified through screening programs and may receive structured follow-up care, patients with alcohol-related cirrhosis may not seek medical attention until they develop symptoms, by which time the disease has often progressed to an advanced stage. Furthermore, alcohol use disorder is frequently accompanied by socioeconomic challenges, mental health comorbidities, and stigma (8), all of which contribute to delayed presentation and reduced access to curative interventions.

Another key factor in this disparity is the availability of antiviral therapies that can effectively suppress or even eliminate viral hepatitis, reducing the risk of HCC development and improving liver function. The advent of direct-acting antivirals (DAAs) for hepatitis C virus (HCV) and nucleos(t)ide analogs for hepatitis B virus (HBV) has significantly changed the natural history of viral cirrhosis (9,10). By decreasing viral replication, these treatments slow fibrosis progression, decrease inflammation, and, in some cases, lead to

fibrosis regression, thereby mitigating the oncogenic potential of chronic hepatitis (11). In contrast, alcohol-related liver disease remains a challenging entity with no pharmacologic intervention capable of reversing liver injury or eliminating the carcinogenic risk. Abstinence is the primary intervention, but its success depends heavily on patient motivation, psychological support, and access to addiction treatment services-factors that are highly variable and difficult to sustain in the long term.

Our findings emphasize the urgent need to enhance HCC surveillance in patients with alcohol-related cirrhosis. Given that current guidelines recommend biannual ultrasound screening for high-risk individuals (12,13), strategies to improve adherence among this population are critical. Potential solutions include integrating hepatology care with addiction services, implementing patient navigation programs, and leveraging digital health tools for appointment reminders and follow-up (14). Additionally, targeted public health interventions that address alcohol dependence and promote awareness of HCC risk may help shift the current paradigm of late-stage diagnosis in this vulnerable group.

Another aspect that deserves attention is the underutilization of liver transplantation in patients with alcohol-related cirrhosis. Despite being a well-established curative option for selected patients with HCC (15), access to transplantation remains limited for those with alcohol-related liver disease due to concerns regarding relapse and post-transplant adherence to medical care. While current selection criteria emphasize sustained abstinence (16), emerging evidence suggests that some patients with alcohol-related HCC may achieve excellent outcomes even with shorter pre-transplant sobriety periods, provided they receive appropriate psychosocial support (17). Expanding transplantation eligibility in carefully selected patients could improve survival rates and offer curative potential in a subset of patients who are otherwise classified as non-curative due to liver dysfunction.

Finally, the disparities observed in our study highlight the need for targeted public health interventions to improve HCC screening and early detection, particularly in high-risk populations. Patients with alcohol-related cirrhosis may benefit from enhanced surveillance strategies that integrate hepatology with addiction medicine, patient navigation programs to facilitate adherence, and digital health tools such as automated reminders for screening appointments. Additionally, raising awareness about HCC risk among primary care providers and implementing outreach programs for underserved populations could help bridge the gap in early diagnosis and improve outcomes in this vulnerable group.

CONCLUSIONS

The significantly higher proportion of non-curative stage diagnoses among patients with alcohol-related cirrhosis underscores the need for improved screening strategies, better patient engagement, and integrated approaches to alcohol use disorder management. Unlike viral hepatitis, where antiviral therapies can modify disease progression and reduce HCC risk, alcohol-related liver disease continues to pose unique challenges that demand a more proactive and multidisciplinary approach.

Our findings reinforce the urgent need for a more proactive, multidisciplinary approach to the detection and management of HCC in patients with alcohol-related cirrhosis. Addressing disparities in surveillance and access to care, refining staging criteria, and optimizing treatment pathways could

significantly improve outcomes for these high-risk patients. Future research should focus on identifying effective interventions to bridge these gaps and reduce the burden of advanced-stage HCC diagnoses.

THE IMPACT OF BARIATRIC SURGERY ON OXIDATIVE STRESS IN OBESE PATIENTS (Abstract): Given the increasing prevalence of obesity and its association with multiple systemic complications, exploring the biological mechanisms underlying this condition has become imperative. Oxidative stress is an important contributor to metabolic dysfunction and chronic inflammation. Bariatric surgery not only induces significant weight loss but may also modulate oxidative balance, offering potential benefits beyond weight reduction. **Aim:** To evaluate and compare the degree of oxidative stress (OS) in the serum of patients with morbid obesity before and after bariatric surgery (BS), in relation to non-obese control subjects. **Materials and methods:** In this longitudinal comparative study, we collected plasma samples from three groups. First, plasma was obtained from 21 patients with a BMI $\geq$ 40 kg/m² (age range: 21-65 years) to assess metabolites involved in oxidative stress (OS). We measured key OS biomarkers, including superoxide dismutase (SOD) activity, malondialdehyde (MDA), as well as total serum protein concentration, which provides additional insight into the systemic metabolic status. Second, plasma samples were collected from healthy individuals with a mean BMI of 22.1 ± 0.8 kg/m², serving as the control group. Three months after bariatric surgery, plasma samples were again collected from the obese patients who attended the follow-up visit, constituting the third group. **Results:** Three months after bariatric surgery, SOD levels showed a partial recovery (0.30 ± 0.04 U/mL), although they remained significantly lower compared to the control group. Regarding lipid peroxidation, a significant reduction in MDA levels was observed in the surgery group compared to the overweight group ($p=0.0004$), suggesting a beneficial effect of the surgical intervention on oxidative stress. Serum protein levels were significantly elevated in obese patients compared to controls and showed a marked decrease after bariatric surgery, reaching values similar to those of the control group ($p<0.05$). **Conclusions:** We have demonstrated the relationship between OS parameters and mediators in people with morbid obesity. Bariatric surgery improves the antioxidant profile and reduces oxidative stress and comorbidities. **Keywords:** BARIATRIC SURGERY, OXIDATIVE STRESS, FREE RADICALS, MORBID OBESITY.

INTRODUCTION

Obesity is a complex disease having an important public health impact worldwide, and its prevalence is increasing. It is the result of an individual complex interaction of factors, including genetic predisposition, diet, metabolism, and physical activity (1). The prevalence of obesity has risen rapidly in Romania. In a study of 2,103 participants, 31.1% were overweight and 21.3% were obese (2).Obesity rates increased with age, peaking at 41.6% among individuals aged 60-79 years (2).

It has been demonstrated that oxidative stress is involved in the pathogenesis of various metabolic, inflammatory or tumoral diseases (3). Oxidative stress plays a crucial role in the pathophysiology of obesity by altering mitochondrial regulatory factors, promoting lipogenesis, and influencing hypothalamic neurons involved in appetite control. Morbid obesity is associated with accelerated atherosclerosis, a chronic vascular disease related to OS and endothelial dysfunction. (4). Obesity disrupts mitochondrial metabolism, leading to increased production of reactive oxygen species (ROS) and oxidative stress. The accumulation of intracellular triglycerides inhibits adenosine nucleotide movement, reducing oxidative phosphorylation and facilitating electron leakage, which generates ROS. These reactive species damage tissues and initiate an inflammatory response that enhances adipokine expression, promotes macrophage infiltration into adipose tissue, and exacerbates lipid disorders through excessive ROS and cytokine production (5) (6). Although oxidative stress contributes to the development and progression of obesity, it is only one of many factors involved in this complex pathology (7). Still, the number of studies examining the oxidative stress in different stages of obesity remains small.

Oxidative stress plays a central role in the metabolic dysregulation observed in obesity, contributing to chronic inflammation and increased risk of metabolic diseases such as metabolic dysfunction-associated steatotic liver disease (MASLD), previously known as non-alcoholic fatty liver disease (NAFLD) (8). MASLD patients often exhibit increased levels of ROS, which impair lipid metabolism and insulin sensitivity. Elevated levels of ROS lead to lipid peroxidation, mitochondrial dysfunction, and insulin resistance, which further exacerbate metabolic complications. Among the key biomarkers of oxidative stress, superoxide dismutase (SOD) serves as a critical antioxidant enzyme that neutralizes superoxide radicals, while malondialdehyde (MDA) acts as a marker of lipid peroxidation. Studies have shown that obese individuals exhibit increased oxidative stress, characterized by decreased SOD activity and elevated MDA levels, which correlate with systemic inflammation and metabolic disturbances (9). Oxidative stress is also recognized as a major factor in the pathogenesis of irritable bowel syndrome (IBS). Studies have shown that both obesity and IBS are associated with gut dysbiosis and immune activation, which exacerbate oxidative stress and increase the risk of metabolic comorbidities (10).

Furthermore, interventions such as bariatric surgery have demonstrated potential in restoring oxidative balance by enhancing SOD activity and reducing MDA levels, ultimately improving metabolic profiles and reducing comorbidities (11).

The aim of our study was to evaluate the specific activity of the peripheral antioxidant SOD and the lipid peroxidation marker MDA in the serum of obesity patients, both before and three months after bariatric surgery, compared to matched control subjects.

MATERIAL AND METHODS

Patients. We conducted a prospective study involving 21 consecutive patients with a confirmed diagnosis of morbid obesity (BMI > 40 kg/m²) (12), all of whom underwent bariatric surgery at the Surgery Department III of St. Spiridon Hospital in Iași, Romania. Among the bariatric procedures performed, seven patients underwent laparoscopic sleeve gastrectomy, whereas fourteen underwent Roux-en-Y gastric bypass. The control group comprised 10 non-obese persons with mean BMI 22.1 ± 0.8 kg/m², in the age group 30 to 35 years.

Inclusion criteria for the obese group (n = 21) included a confirmed diagnosis of morbid obesity (BMI ≥ 40 kg/m²), eligibility for bariatric surgery, an age range between 21 and 65 years, and the provision of informed written consent to participate in the study. Inclusion criteria for the control group were: absence of alcohol abuse, no history of infectious diseases, and no use of vitamin supplementation. In addition, participants continued their usual medication regimen prior to testing.

Exclusion criteria for both the obese and control groups included: current use of antioxidants or anti-inflammatory medications, recent surgery or trauma (within the past 6 months), pregnancy or lactation, and adherence to special diets (e.g., ketogenic, vegan, or detox regimens) that could influence oxidative stress parameters.

All participants provided written, informed consent. The study was approved by the local ethics committee.

Methods. Blood samples were collected in the morning, prior to breakfast, from both the baseline group and the patients who returned for the 3-month follow-up. Samples were allowed to clot and were centrifuged immediately thereafter. Serum was aliquoted into Eppendorf tubes and stored at -40ºC prior to measurement. All samples were measured in duplicate and averaged.

Determination of superoxide dismutase (SOD)

SOD activity was determined using the SOD Determination Kit (Fluka, 19160) based on the reduction of the water-soluble tetrazolium salt WST-1, which yields a formazan dye upon reaction with superoxide anions. The reaction is mediated by xanthine oxidase, and its inhibition by SOD reflects the enzymatic activity. Each reaction was carried out in a 96-well plate by mixing the sample with WST Working Solution and Enzyme Working Solution, followed by incubation at 37°C for 20 minutes. Absorbance was measured at 450 nm using a microplate reader. SOD activity was calculated as the percentage inhibition of the colorimetric reaction, according to the formula provided by the manufacturer, and results were normalized to the protein concentration, expressed as SOD activity units.

Determination of malondialdehyde (MDA)

MDA levels were determined using the Lipid Peroxidation (MDA) Assay Kit (MAK568). Briefly, 20 µL of serum or plasma was mixed with 500 µL of 42 mM sulfuric acid, followed by the addition of 125 µL phosphotungstic acid solution and vortex mixing. After incubation at room temperature for 5 minutes, the samples were centrifuged at 13,000 x g for 3 minutes, and the supernatant was discarded, retaining the pellet. The pellet was resuspended in a mixture of 2 µL BHT solution and 100 µL cold ultrapure water, adjusting the final volume to 200 µL. The assay reaction was performed by adding 600 µL of TBA solution to 200 µL of sample or standard, incubating at 95°C for 1 hour, and cooling to room temperature. The absorbance was measured at 532 nm, and

MDA concentrations were determined using a standard curve, with results expressed as nmol/mL.

Determination of proteins level

Serum protein levels were measured using the Bradford method, which relies on the specific binding of Coomassie Brilliant Blue G-250 dye to proteins, resulting in a quantifiable color change. This assay measures the absorbance at 595 nm, allowing protein concentration to be determined by comparing sample absorbance to a standard calibration curve, typically generated with bovine serum albumin (BSA). The Bradford method is valued for its rapidity, high sensitivity, and low reagent consumption; however, its accuracy may be affected by the presence of detergents or other substances that interfere with dye binding (13).

TABLE I.

Demographic and clinical data in control, baseline, and post-surgery groups (3 months after surgery)

	Control (n=10)	Baseline (n=21)	After 3 Months Group (n=10)	p Value[b]
Age [a]	32.2 ± 5.95	37 ± 1.30	41.2 ± 15.1	
Gender (Male/Female)	3/7	1/20	0/10	0.04

BMI [a]	29 ± 1.8	50.5 ± 6.3	39.0 ± 7.6	0.00085

a. Each value represents mean ± standard deviation b. Analysis of covariance

RESULTS

Demographic and clinical characteristics of participants

A total of 31 participants were included in the study, divided into three groups: the control group (n = 10), consisting of non-obese individuals with a mean BMI of 22.1 ± 0.8 kg/m²; the baseline group (n = 21), composed of patients with morbid obesity (BMI > 40); and the post-surgery group, consisting of only a subset of the initial obese cohort (n = 10), evaluated three months after undergoing bariatric surgery. The mean age of the participants ranged between 30 and 37 years, with a predominance of females, especially in the obese group (1 male and 20 females). Chronic treatments were reported in 42.9% of obese patients, most commonly addressing hypertension, type 2 diabetes mellitus (T2DM), and gastroesophageal reflux disease (GERD). Regarding medication, metformin and pantoprazole were each used by 14.28% of patients, while selective β1-blockers and levothyroxine sodium were also noted. After surgery, patients experienced a marked decrease in BMI (from 50.5 ± 6.3 to 39.0 ± 7.6), suggesting a significant early weight loss following the intervention. The analysis of covariance showed that the patients from overweight group did not differ significantly from the healthy comparison subjects with respect to age, smoking habits (tab. I).

Changes in SOD activity post-surgery

Regarding the specific activity of SOD, which is the first line of defense against oxidative stress development, we noticed a significant decrease in the overweight group compared to the control group (Fig. 1). The control group exhibited the highest SOD activity levels (0.58 ± 0.13 U/mL), whereas the overweight group demonstrated a marked reduction (0.20 ± 0.07 U/mL).

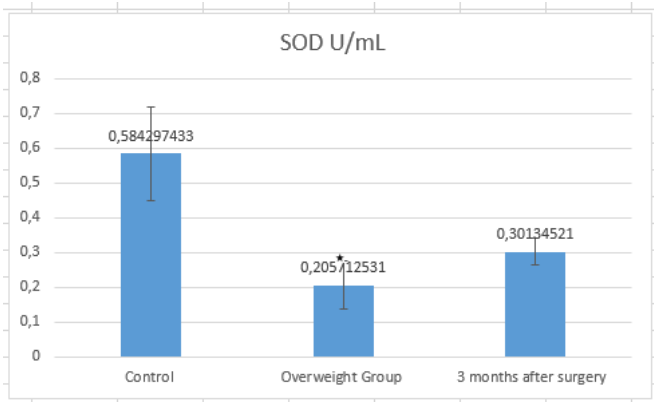

Fig. 1. Superoxide dismutase specific activity in the serum of Control (n=10) Overweight (n=21) and 3 months after surgery (n=10) patients.
The values are expressed as mean ± SEM (Standard Error on the Mean) $^{*}p = 0.03$

Three months after bariatric surgery, SOD levels showed a partial recovery (0.30 ± 0.04 U/mL), but remained significantly lower than in the control group. Post hoc analysis confirmed significant differences between the control and overweight groups ($p<0.05$), while the difference between the post-surgery and overweight groups was also statistically relevant ($p <0.05$), suggesting an improvement in antioxidant defense following surgical intervention.

Lipid peroxidation changes

Concerning the lipid peroxidation, a significant increase of the MDA concentration was observed in the overweight group compared with the control group ($p < 0.05$). The comparison between the control and surgery groups revealed a non-significant difference ($p = 0.0539$), indicating that after surgery, MDA levels approximate those of the control group, suggesting a potential restoration to baseline values (fig. 2).

Also, the comparison between the overweight and surgery groups showed a significant difference ($p = 0.0004$), suggesting that the surgical intervention led to a notable reduction in MDA levels compared to the overweight group. The post-hoc analysis for MDA revealed significant differences, indicating that MDA levels were higher in the overweight group and significantly decreased after surgery, approaching control levels.

Protein level changes post-surgery

The assessment of protein levels in this study offers crucial insights into the metabolic profile and physiological adaptations of both obese individuals and those who have undergone bariatric surgery. Regarding protein levels, a significant increase was observed in the overweight group compared to the control group ($p < 0.05$). The comparison between the control and surgery groups revealed a non-significant difference ($p = 0.8316$), indicating that after surgery, protein levels approximated those of the control group, suggesting a potential return to baseline values (fig. 3). Additionally, the comparison between the overweight and surgery groups showed a significant difference ($p < 0.05$), indicating that surgical intervention led to a notable reduction in protein levels compared to the overweight group. The post-hoc analysis for protein levels confirmed significant differences, demonstrating that protein

concentrations were higher in the overweight group and significantly decreased after surgery, reaching levels comparable to the control group.

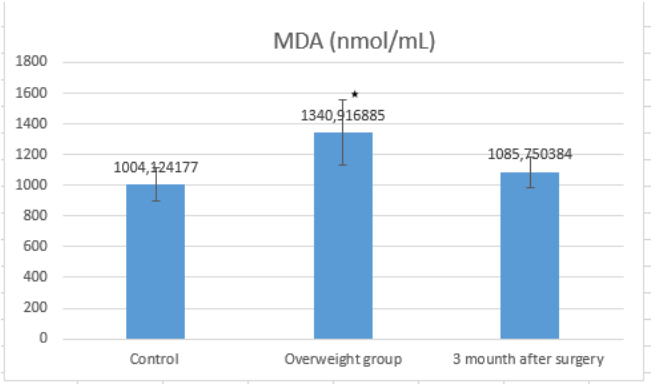

Fig. 2 Malondialdehyde specific activity in the serum of Control (n=10) Overweight (n=21) and 3 months after surgery (n=10) patients. The values are expressed as mean ± SEM (Standard Error of the Mean) $^{*}p < 0.05$

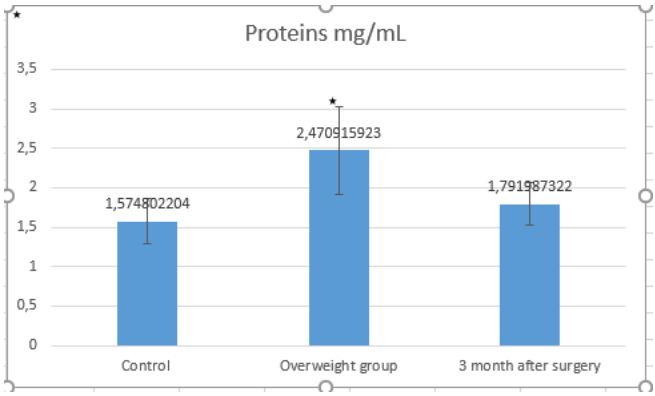

Fig. 3 Protein levels in the serum of Control (n=10) Overweight (n=21) and 3 months after surgery (n=10) patients. The values are expressed as mean ± SEM (Standard Error of the Mean) $^{*}p < 0.05$.

Correlations between oxidative enzymes and protein levels

Analyzing the correlation between the two measured enzymes with the value of protein in serum, we observed in the case of SOD a very weak, non-significant correlation **(**n = 41, r = 0.029, p = 0.859), suggesting that SOD levels do not show a meaningful relationship with protein concentration. This contrasts with studies where SOD was moderately correlated with inflammatory markers (e.g., CRP) (14), indicating that additional factors may influence these oxidative stress parameters in our study population. A small, non-significant positive correlation in the case of MDA, (n = 41, r = 0.205, p = 0.199), indicating that MDA levels are slightly associated with protein concentrations, but not at a statistically significant level.

DISCUSSION

Oxidative stress is a key factor in obesity-related metabolic dysfunctions (1). In this study, we assessed oxidative stress biomarkers in three groups: a control group, an obese group before bariatric surgery, and the same obese individuals three months post-surgery. SOD levels were significantly elevated in obese patients compared to controls, suggesting a compensatory enzymatic response to increased oxidative stress. However, three months post-surgery, SOD levels decreased, indicating a partial recovery of redox homeostasis. Similarly, MDA, a marker of lipid peroxidation, was highest in obese patients and decreased following bariatric surgery, though it remained elevated compared to controls. Additionally, protein levels were significantly lower in obese individuals but showed a modest increase post-surgery.

In the group of overweight patients, significantly elevated protein levels suggest the presence of a chronic systemic inflammatory status, characteristic of obesity. This may be correlated with oxidative stress and altered liver function (15). This aspect was highlighted a study (16), which shows that oxidative stress associated with mitochondrial dysfunction enhances the glycation of hepatic proteins, thereby exacerbating inflammation-induced liver damage.

At three months postoperatively, protein levels were significantly reduced compared to the overweight group, suggesting either a normalization of protein metabolism through a balance between protein synthesis and degradation, or a physiological adaptation to the new metabolic conditions imposed by dietary restrictions and post-bariatric hormonal changes. This was also highlighted in a comparative study (17) that analyzed changes in the protein profile of two groups: one following a hypocaloric diet and the other undergoing bariatric surgery. A significant decrease in leptin levels was observed in the surgical group, suggesting improved appetite regulation postoperatively ($p = 0.005$).

As shown in Table 1, 19% of the patients in our study have type II diabetes, a condition known to be associated with increased oxidative stress (18). This relationship is further supported by a study investigating lipid peroxidation and protein oxidation levels (19), which demonstrated that diabetes, particularly when combined with glucose-6-phosphate dehydrogenase (G6PD) deficiency, leads to a significant increase in MDA levels, a key marker of oxidative stress. In patients with G6PD deficiency, MDA levels were elevated by approximately 28-41%, indicating an enhancement of lipid peroxidation under the combined influence of these pathological conditions. The postoperative increase in SOD levels observed in our patients, including those with type II diabetes, may contribute to a hypoglycemic effect. This is supported by experimental evidence from a diabetic rat model (20), where elevated levels of MDA and GSSG/GSH ratio indicated pronounced oxidative stress. Oral administration of liposome-embedded SOD (L-SOD) in these rats led to a reduction of MDA by 34.74% and GSSG/GSH ratio by 45.4%. After four weeks of intervention, blood glucose levels significantly decreased in the treated groups, suggesting a potential role of SOD in improving glycemic control through attenuation of oxidative stress.

The analysis of LPO levels, assessed via MDA content, has yielded contradictory findings. In our study, MDA levels were reduced three months postoperatively, indi-

cating an improvement in oxidative status. Similar results were reported by Bell *et al.*, where hepatic MDA content-a marker of lipid peroxidation-decreased significantly after bariatric surgery, from 34.9% ± 18.3% to 22.9% ± 13.8% (21). However, the evaluation of long-term outcomes appears less favorable. A separate study (22) assessing global oxidative stress markers found that TBARS (thiobarbituric acid reactive substances), an indirect indicator of MDA levels, did not remain decreased four years after surgery. In some patients, TBARS levels even increased, suggesting a potential re-emergence of oxidative stress. Contributing factors identified included dietary habits, physical activity levels, and the use of antioxidant supplements.

These findings suggest that BS contributes to a reduction in oxidative stress but does not fully restore normal metabolic balance within three months. Further long-term studies are needed to evaluate the full extent of oxidative stress recovery following bariatric intervention.

The results of our study are consistent with previous findings by Min *et al.* (22) Horn *et al.*, (11) and Cabrera *et al.*, (23) which demonstrated that bariatric surgery contributes to a reduction in oxidative stress in obese patients, primarily through decreased LPO and enhanced antioxidant defense mechanisms.

There are several limitations inherent in this study. First, the relatively small sample size may limit the generalizability of our findings. Second, not all 21 patients returned for follow-up at three months postoperatively, which could have influenced the consistency of the longitudinal comparisons. Additionally, individual variability in oxidative stress markers may have been influenced by unmonitored factors such as dietary changes, physical activity levels, or unreported supplement intake during the postoperative period.

CONCLUSIONS

Given the changes observed in oxidative stress markers following bariatric surgery, our study confirms that excessive body mass significantly contributes to elevated production of ROS. The notable decrease in MDA levels and partial recovery of SOD activity three months postoperatively suggest that surgical intervention, combined with weight loss, contributes to the restoration of redox balance. Furthermore, the normalization of protein levels may indicate an attenuation of systemic inflammation and improved metabolic function.

THE RELATIONSHIP BETWEEN DENTAL ANXIETY AND THE SOCIAL IMPACT OF ORAL DISORDERS ON WELL-BEING IN PATIENTS ATTENDING A PUBLIC DENTAL EMERGENCY UNIT. A SINGLE-CENTER STUDY (Abstract): **The aim** of this study was to identify the characteristics of patients who access public dental emergency units in the Oradea area, in relation to the presence of dental anxiety and the impact of oral disorders on general well-being. **Materials and methods**: A total of 105 patients admitted to the emergency dental unit were included in this study. Demographic data, socioeconomic information, medical problems, and self-evaluations of oral health were recorded. To evaluate the social impact of oral disorders on well-being, *The Oral Health Impact Profile* was applied, and the *Norman Corah's Dental Anxiety Scale* was used to score the dental anxiety level. Statistical analysis was performed using the IBM Statistical Package for Social Sciences, version 26. **Results**: More than 10% of the patients showed high and severe dental anxiety. No significant differences in participants' sex, marital status, or living environment were found to be related to *Norman Corah's Dental Anxiety Scale.* Women registered higher scores than men on the physical, psychological and social disability subscales of *The Oral Health Impact Profile*. The OHIP score was strongly and positively correlated with the DAS-R score. The results related to the level of education, financial income, dental hygiene, alcohol consumption, and analgesic use are discussed. **Conclusions**: The impact of oral health on the physical, psychological, and social quality of life is important. In prevention campaigns, partners and institutions should consider different factors to manage the level of dental anxiety and increase the quality of dental health. **Keywords:** DENTISTRY, DENTAL EMERGENCY UNIT, PUBLIC HOSPITAL, DENTAL ANXIETY, ORAL DISORDERS, QUALITY OF THE ORAL HEALTH.

INTRODUCTION

The World Health Organization advocates coverage of healthcare costs for all categories of people. (1) Studies in medical sociology and health management have shown that several factors affect the use of health services, including costs, level of health education, and distance from the health center. Sociological models related to health have been considered to identify

vulnerable populations and provide them with easier access to preventive, diagnostic, and treatment services.

Andersen's model provides a theoretical framework for understanding and predicting the use of health services. Over the years, three main determinants have been considered: a) *predisposing factors* that determine the inclination or likelihood of an individual to use health services when they need them, such as demographic characteristics (age, sex, and family size), social characteristics (education, income and marital status) and beliefs about health (attitudes, values, and perceptions about health and illness); b) *enabling factors* are resources or barriers that facilitate or hinder the use of health services. These can be individual (income and health insurance) or community-level or community resources (availability and accessibility of health services in a geographic area), and c) *needs* referring to the perceived or assessed need for care, determined conditions, symptoms, or physical limitations (2-4).

In addition to interventions to relieve pain, some studies have shown that patients access emergency dental services for psychological reassurance, that the problem is not serious, and seek counseling. Therefore it is important for dentists to offer psychoemotional support in addition to medical intervention and in terms of the duration of the intervention. Communication in emergency services is extremely important, especially if the patient is in a serious condition due to avoidant behavior or the presence of phobia. In addition, as we have shown above, it is possible that the patient presented to the emergency system because the postponement of care was determined by poor socioeconomic conditions or the distance from a dental care center (5-8).

Poor untreated dental health leads to a low quality of life, and most oral diseases tend to be progressive and cumulative without proper intervention. Oral health determines general quality of life, and ensures good physical, psychological and social balance (9).

The goals of this study were to shape the profile of the patient that accesses the public dental emergency units in the Oradea area, in relation to the presence of dental anxiety and to identify the impact of oral disorders on general well-being. A previous study by the research team identified oral behaviors among patients consulting emergency units (10). The present analysis of data will focus on: a) the relationship between stress and various aspects of dental health and dental health-related behaviors; b) differences in dental anxiety level based on demographic and socioeconomic characteristics; c) the relationship between dental health behaviors and dental anxiety; d) the relationship between satisfaction with oral health and various aspects of functional limitations, physical pain, and psychological discomfort; and e) to identify whether the subscales of the oral health profile (functional limitations, physical pain, psychological discomfort, physical disability, psychological disability, social disability, and obstacles) are significant predictors of dental anxiety.

MATERIALS AND METHODS

Participants and Data Collection. In 2021, 2026 patients were accepted at the dental emergency unit of the Oradea Emergency, a public hospital in North-Western Romania. Between June 20th and July 20th, 197 patients were registered, and printed questionnaires were distributed to them before consultation. All participants were

informed about the purpose of the research and that the data collected would be confidential. No incentives were provided to participants in the study. To ensure the confidentiality of personal data, the surveys were collected in a sealed box located in the main hall.

The inclusion criterion was patients older than 18 y.o. who fully filled in questionnaires. Only questionnaires filled in in person were accepted in order to select patients (literate, no cognitive or mental disability, self-signing informed consent). A total of 105 questionnaires were included in this study.

Instruments. The questionnaire collected data on demographic characteristics, financial status, health-related behaviors, level of stress, quality of dental life, consumption of alcohol or tobacco, dental hygiene routine, and use of pain drugs. Supplementary data regarding diagnostic and self-rated items, focusing on identifying the level of satisfaction with health, were also collected.

Two psychological tools were added to investigate the presence of dental anxiety and impact of oral health-related problems on general well-being.

Norman Corah's Dental Anxiety Scale (DAS-R) is a validated instrument used by dentists to assess the level of dental anxiety in patients. The scale consists of four questions, and each item is constructed as a scenario with different possible reactions (for example: If you had to go to the dentist tomorrow for a check-up, how would you feel about it? a) I would look forward to it as a reasonably enjoyable experience. b) I would not care about one way or the other. c) I would be a little uneasy about this. d) I would be afraid that it will be unpleasant and painful. e) I would be very frightened about what the dentist would do). Responses were scored on a scale of 1 to 5, with a maximum total score of 20. The score obtained by the patient generates the following situations: 912 points = *moderate anxiety level* with some specific stressors that should be discussed and managed together with the patient, 1314 points = *high anxiety* and a score over 1520 = *severe anxiety (or phobia*) (11). In the present study, the Cronbach's alpha was 0.898, indicating good internal consistency.

The Oral Health Impact Profile (OHIP-14), developed by Slade in 1997 (12) is a self-administered questionnaire consisting of 14 items designed to measure the social impact of oral disorders on well-being. The questionnaire was organized into seven dimensions, each represented by two questions. These dimensions are: a) functional limitation, b) physical pain, c) psychological discomfort, d) physical disability, e) psychological disability, f) social disability, and g) handicap. Participants were asked to rate the frequency of specific problems they experienced, relating to these dimensions in their daily lives. Responses were recorded on a 4-point Likert-type scale, where 0 = *never*, 1 = *almost never*, 2 = *occasionally*, 3 = *often*, and 4 = *very often*. Each dimension's score ranged from 0 to 8 and was calculated by summing the scores of the two corresponding items. The total OHIP-14 score was the sum of all individual item scores, ranging from 0 to 56. Lower scores indicate a higher quality of life, with scores closer to 0, suggesting a minimal impact of oral health issues on daily life. Conversely, higher scores (e.g., eight for the total score for each dimension and 56 for the total score for the OHIP-14) indicated a more significant negative impact on quality of life.

In the present study, Cronbach's alpha was 0.710 for the functional limitation dimension, 0.670 for the physical pain dimension, 0.817 for the psychological discomfort dimension, 0.845 for the physical disability dimension, 0.811 for the psychological disability dimension, 0.824 for the social disability dimension, and 0.648 for the obstacles dimension. A Cronbach's alpha of 0.932 for all items suggested greater internal consistency.

Statistical Analyses. The statistical analysis was conducted using IBM Statistical Package for Social Sciences (SPSS) version 26 (SPSS Inc., Chicago, IL, USA). Means and standard deviations (SD), as well as frequencies and percentages, were used for descriptive analysis of the data. An independent T test was performed for comparative analysis. Correlation analysis was done using Pearson's correlations, and the level of statistical significance was set at $p < 0.05$.

Ethical Approval. The present study was conducted in accordance with the Declaration of Helsinki, and the research protocol was approved by the Ethical Committee of the Emergency Clinical Hospital of Oradea, Bihor County, Romania (No. 14518/16.06.2021).

RESULTS

Sociodemographic and health-related data. The participants included in the research are 55 female (52.4%) and 50 males (47.6%), aged 37.03 ± 14.45, with a minim of 18 and a maximum of 84 years old. Most participants were from urban areas (N = 64, 61%). Almost three-quarters declared that they were employed (N = 73, 69.5%). Regarding their level of education, we identified that N = 29 (27.6%) had a middle school education level, N = 60 (57.1%) had graduated from high school and N = 16 (15.2%) had a university level of education. By investigating their financial status, we found that 86 (82.8%) earned less than 3,000 RON (600 euros) per month.

A series of items investigated the behaviors associated with oral health and daily dental routines. More than a quarter of them (N = 30, 28,6%) declared that they consumed alcohol, and more than half of the participants sustained that they did not smoke (N = 66 (62.9%). Ten patients (9,5%) presented with abscesses and 5 (4,8%) were diagnosed with gingivitis.

Regarding their teeth brushing routine, we identified that around one-third of them brushed their teeth daily, in the morning or at night, with morning brushing being more frequent than evening brushing. By asking participants to rate their level of satisfaction with dental health on a scale from 1 (very dissatisfied) to 5 (extremely satisfied) we obtained an M = 2.97 ± 1.11. The detailed results of the dental hygiene routine are presented in first table.

TABLE I.
Dental Health Routine

	Do you brush your teeth in the morning?	Do you brush your teeth in the evening?
Never	0	0
Very rare	6 (5.7)	11 (10.5)
Sometimes	21 (20.0)	28 (26.7)
Almost every morning	30 (28.6)	32 (30.5)
Every morning	48 (45.7)	34 (32.4)

[1] Number of answers (N) and percentage (%)

Dental Anxiety and Oral Health-Related Quality of Life

Corah's Dental Anxiety Scale - the total score for DAS-R scale was M = 8.51 ± 3.34, ranging from 4 (16.2%) to 20 (1.0%). More than one-third of participants had

moderate levels of anxiety (tab. II).

TABLE II.
Results for the DAS-R scale[1]

DAS-R Scale	N (%)
Mild level of anxiety	50 (47.6%)
Moderate anxiety	44 (41.9%)
High anxiety	7 (6.7%)
Severe anxiety/Phobia	4 (3.8%)

[1] Number of answers (N) and percentage (%)

No significant differences were found in terms of participants' sex, marital status, or living environment.

There was a statistically significant difference in the mean DAS-R score between those who very rarely brush their teeth in the morning and those who brush their teeth every morning - 0.35 (95% CI, 0.22 to 6.36), $t(51) = 2.155$, $p = .036$; those who rarely brush their teeth in the morning have a higher level of anxiety (11.17 ± 4.75) compared to those who have oral hygiene every morning (7.87 ± 3.36).

Oral Health-Related Quality of Life Scale: The analysis of answers showed that respondents had low levels of oral health impact. The total OHIP-14 score was, on average, M = 17.12 ± 11.46, with scores ranging from 0 (3.8%, N = 4) to 53 (1%, N = 1) (tab. III).

An independent-samples t-test was run to determine if there were differences in the OHIP scores between males and females.

-women reported a higher mean for total score of social impact of oral disorders on well-being (19.96 ± 10.73) compared with men (14.00 ± 11.52), a statistically significant difference of 5.96 (95% CI, 10.27 to 1.65), $t(103) = -2.745$, $p = .007$,

-women reported a higher mean number of psychological discomfort (4.09 ± 1.99) compared with men (2.92 ± 2.18), a statistically significant difference of 0.30 (95% CI, -1.97 to -0.36), $t(103) = -2.873$, $p = .005$,

-women reported higher scores for social disability (2.63 ± 1.92) compared with men (1.54 ± 1.83), a statistically significant difference of 0.86 (95% CI, -1.82 to -0.36), $t(103) = -2.980$, $p = .004$,

-women reported a higher mean number of psychological disabilities (3.01 ± 2.13) compared with men (2.16 ± 1.83), a statistically significant difference of 0.43 (95% CI, -1.63 to -0.83), $t(103) = -2.197$, $p = .030$.

TABLE III.
Scores for OHIP subscales

OHIP subscales	Items	Means ± Standard deviation
Functional Limitation	*Have you had trouble pronouncing any words because of problems with your teeth, mouth, or dentures?*	M = 1.39 ± 1.76
	Have you felt that your sense of taste has worsened because of problems with your teeth, mouth, or dentures?	
Physical Pain	*Have you experienced pain in your mouth?*	M = 3.12 ± 2.12
	Have you found it uncomfortable to eat any food because of problems with your teeth, mouth, or dentures?	
Psychological Discomfort	*Have you been self-conscious of your teeth, mouth, or dentures?*	M = 3.53 ± 2.15
	Have you felt tense because of problems with your teeth, mouth, or dentures?	

OHIP subscales	Items	Means ± Standard deviation
Physical Disability	*Has your diet been unsatisfactory because of problems with your teeth, mouth, or dentures?*	M = 2.61 ± 2.30
	Have you had to interrupt meals because of problems with your teeth, mouth, or dentures?	
Psychological Disability	*Have you found it difficult to relax because of problems with your teeth, mouth, or dentures?*	M = 2.60 ± 2.03
	Have you been slightly embarrassed because of problems with your teeth, mouth, or dentures?	
Social Disability	*Have you been slightly irritable with other people because of problems with your teeth, mouth, or dentures?*	M = 2.11 ± 1.95
	Have you had difficulty doing your usual job because of problems with your teeth, mouth or dentures?	
Handicap	*Have you felt that life in general was less satisfying because of problems with your teeth, mouth, or dentures?*	M = 1.73 ± 1.75
	Have you been completely unable to function because of problems with your teeth, mouth, or dentures?	

There were differences in the OHIP scale depending on the use of analgesics. People taking painkillers reported a higher OHIP score (20.54 ± 11.46) compared with people who did not take painkillers (12.38 ± 9.73), a statistically significant difference of 0.75 (95% CI, 3.92 to 12.38), $t(103) = 3.826$, $p < .001$.

There was a statistically significant difference in the mean OHIP scale scores between those who very rarely brushed their teeth in the morning and those who brushed their teeth every morning - 0.85 (95% CI, 1.79 to 19.58), $t(51) = 2.413$, $p = .019$, those who rarely brushed their teeth in the morning had a higher OHIP score (26.50 ± 9.81) than those who brushed their teeth every morning (15.80 ± 10.26).

The results showed differences in OHIP scores between those who did not drink alcohol and those who drank alcohol very rarely. Respondents who did not drink alcohol reported a higher OHIP score (19.00 ± 11.52) than respondents who drank alcohol very rarely (12.66 ± 10.25), a statistically significant difference of 0.33 (95% CI, 0.81 to 11.85), $t(94) = 2.277$, $p = .025$). Physical pain was negatively correlated with alcohol consumption ($r = -0.27$, $p = 0.005$) and analgesic pill use ($r = -0.35$, $p < 0.001$), indicating that as physical pain increased, alcohol and toothache medication consumption decreased.

The DAS-R score was negatively correlated with the degree of satisfaction regarding dental health ($r = -0.27$, $p = 0.005$), indicating that the higher the level of dental anxiety, the less satisfied the participants were with the health of their teeth.

The OHIP score was strongly positively correlated with the DAS-R score ($r = 0.46$, $p < 0.001$) in the sense that the higher the level of dental anxiety, the greater the social impact of oral disorders on well-being.

Statistical analysis of the data revealed that the OHIP score was negatively corre-

lated with the degree of satisfaction regarding dental health ($r = -0.40$, $p < 0.001$) and income ($r = -0.27$, $p = 0.005$) indicating that the greater the impact of dental health on patients' well-being, the less satisfied they are with their dental health and the lower their income.

Positive correlations were observed between the OHIP score and the intensity of pain felt by patients ($r = 0.23$, $p = 0.015$, indicating that the greater the social impact of dental health on patients' well-being, the higher the pain felt by patients.

A negative correlation between functional limitation and the level of education of the patients ($r = -0.28$, $p = 0.006$) was identified, in the sense that the higher the functional limitation, the lower the level of education.

There was a negative correlation between physical disability and abscess diagnosis ($r = -0.20$, $p = 0.032$), indicating that as physical disability increased, abscess diagnosis decreased.

DISCUSSION

Our results are similar to those of Frichembruder *et al*. (13), who identified that greater use of the emergency service was registered by people in great pain, usually women and adults, coming from urban areas, having a lower income, and being less educated.

In our study, women seemed to be more affected than men in terms of social and psychological disabilities and presented with higher psychological discomfort. Therefore, in general, they are more psychologically and socially affected by poor oral health. These results are similar those of Shamim *et al*. (14), Skośkiewicz-Malinowska *et al*. (15) and Närhi *et al*. (16) who identified sex differences in the impact of oral health among men and women. Aesthetic reasons are related to the level of satisfaction with body image, meaning that women will be more preoccupied with their dental health to maintain satisfaction with their body image.

Oral health has been defined as "a standard of health of the oral and related tissues that enables an individual to eat, speak or socialize without active disease, discomfort or embarrassment and which contributes to general well-being". (17) Women were found to be more preoccupied than men when it came to using toothpaste and mouthwash. Brushing twice a day and using a mouthwash were statistically higher in female than male. (18) A low level of satisfaction with body image is closely linked to satisfaction with facial aesthetics, including teeth. Studies have shown that facial images are among the most important aspects that make patients feel satisfied with their physical appearance. When it comes to the face (nose, eyebrows, lips, cheekbones and teeth), the teeth occupy the main place. Therefore, it is understandable why women who are dissatisfied with the appearance and health of their teeth have lower overall satisfaction with their body image. Thus, a low level of satisfaction with body image generates a high level of psychological discomfort and psychological and social disabilities.

We found that the DAS-R score was negatively correlated with the degree of satisfaction with dental health, and that patients with a higher level of anxiety rarely brushed their teeth in the morning. These results can be explained by the vicious circle in which a patient with dental anxiety finds themselves. Although some studies

have shown that patients with dental anxiety avoid regular check-ups at the dentist, invest heavily in expensive products to care for their teeth, and take over-the-counter medications to reduce dental pain, they still do not have proper dental hygiene. Teeth brushing is an important step in oral hygiene. Brushing less often results in poorer oral health, which subsequently results in poorer overall health (due to consequences on overall health, such as oral, cardiovascular, and digestive diseases). Therefore, people are less satisfied with their health and body image. Folayan *et al*. (19) showed that the frequency of toothbrushing during the pandemic decreased as the psychological wellbeing increased.

Cohen *et al*. (20) identified that people with high levels of dental anxiety, despite ongoing concerns about oral health, have poor oral quality of life. Winkler *et al*. (21) found a significant correlation between high dental anxiety levels and reduced toothbrushing behavior. The team also found that the use of dental solutions was not affected by the intensity of anxiety. However, in general, a substantial decline in quality of life was identified.

Other studies have shown that, although younger female patients reported higher levels of dental anxiety, the desire for a perfect facial selfie may reduce dental neglect behavior. (22)

The results of this study showed that more than 10% of the participants had high and severe levels of dental anxiety. The prevalence of dental anxiety in the general population varies between 4% and 20%, regardless of the population, culture, or country. (23) Our study revealed no differences in variables such as sex, marital status or living environment. Other studies have shown that women present higher levels of dental anxiety than men do. (24)

Strengths and limitations: The results of this study are important because they outline a profile of patients accessing emergency services, thus enabling dentists to be prepared to care for this category of patients. Sociodemographic and personality factors must be considered when providing medical services, to ensure the best possible care and a higher level of patient satisfaction. As a limitation of this study, we note that the research was conducted during the COVID-19 pandemic, when access to dental services was restricted or diminished. Therefore, it is possible that patients who accessed emergency dental services were forced to do so (due to lack of access, worsening oral health, etc.) which is one of the explanations why, in general, the patients in the study did not present high scores on the scales used. Finally, as this was a single-center study, the results cannot necessarily be generalized to the entire population as it was an urban university center. It is likely that in areas with no access to dental services, differences in the characteristics of the investigated group would appear.

Reflections and Planning. Identifying the sociodemographic and psychological characteristics of patients accessing dental services, along with information regarding the presence of dental anxiety and the psychological and social impact that poor oral health has on the patient's overall health and satisfaction with general health and body image, is important. The results make us more aware of the usefulness of training dentists to work with different social categories and treat patients who present with dental anxiety.

CONCLUSIONS

The reasons why patients end up in the dental emergency system are diverse, including painful incidents, lack of hygiene behaviors, inability to access medical services (due to low health education or poor financial situation), neglect of dental health, and high dental anxiety scores that encourage patients to avoid regular check-ups. The impact of oral health on the physical, psychological and social quality of life is important. In prevention campaigns, partners and institutions should consider all factors that can diminish the level of oral health and, implicitly, the patient's health in general.

CONFLICT OF INTERESTS AND FUNDING

The authors declare no conflict of interests. The research did not receive external funding.

ADVANCING TRAINING FOR GRIGORE T. POPA UNIVERSITY OF MEDICINE AND PHARMACY IASI ENTRANCE EXAMINATION, BASED ON EDUCATIONAL, EMOTIONAL, AND SOCIAL DATA OF FUTURE CANDIDATES (Abstract): The aim of this article is to evaluate the perception of future candidates at the Grigore T. Popa University of Medicine and Pharmacy Iasi regarding the initiative of our institution to organize free preparatory courses in human anatomy and physiology for the admission exam. Secondary objectives included characterizing participants' demographics, educational backgrounds, options for the entrance exam, learning effort and engagement patterns. **Materials and methods:** The study included 119 voluntary participants over two consecutive academic years (60 in 2024, 59 in 2025) who provided explicit consent for anonymous data processing. In 2023-2024, preparatory courses were conducted in an intensive format (March-May 2024), while in 2024-2025, the program was extended to a more in-depth format (October 2024-May 2025). Both courses comprehensively covered all 23 chapters of Barron's Human Anatomy and Physiology textbook. A Google Forms questionnaire assessed multiple domains: demographics, geographical domicile, educational background, time allocation to study examination subjects, and perceived difficulty of specific anatomical topics (embryology, spatial relationships between structures). Participants rated course usefulness on a 5-point Likert scale (1 = "Not useful" to 5 = "Very useful"). Data analysis employed descriptive and comparative statistics. Complete anonymized raw data, statistical analyses with correlations, and supplementary materials (> 50 pages) are publicly available via Mendeley Data, a subsidiary of Elsevier (DOI: 10.17632/2y8nyy4yyy.1). **Results:** Participants had a mean age of 18.96 years (median 18), with 91.6% selecting General Medicine as their first choice. The cohort comprised 54.6% current high school students and 14.3% university graduates seeking career transition. Over 60% of participants allocated 50-90% of their total study time to admission exam preparation. Geographic diversity was observed, with 26.1% of participants traveling from neighboring counties. Regarding course usefulness, a very high proportion of participants rated the courses as "Useful" or "Very useful," with a slight increase from 80.0% in 2024 to 83.1% in 2025. Notably, the proportion rating the courses as "Very useful" increased from 45.0% to 61.0% between years, reflecting the program's ongoing refinement. **Conclusions:** The highly positive feedback from participants validated the preparatory program's effectiveness and triggered informed evidence-based expansion from an intensive to an adequately-paced format. Anonymous questionnaires proved effective for capturing multiple

dimensions of participants' perception regarding study effort and commitment. Our university pre-admission training initiative demonstrates institutional responsiveness to learner needs and provides a replicable model for other medical universities. **Keywords:** ANATOMY AND PHYSIOLOGY, FREE PREPARATORY COURSES, MOTIVATION, LEARNING PROGRAM, SATISFFACTION, ADMISSION EXAM, MEDICINE.

INTRODUCTION

The admission examination for medical and dental medicine faculties represents a critical milestone for high school graduates and constitutes a rigorous filter in selecting the most qualified candidates. Up to and including the summer of 2022, this exam at Grigore T. Popa University of Medicine and Pharmacy Iasi was based on the 11th-grade high school textbook for Anatomy and Physiology. Beginning with the July 2023 admission cycle, the curriculum transitioned to Barron's Human Anatomy and Physiology textbook by Barbara Krumhardt and I. Edward Alcamo, translated and republished in 2022 by University Press of George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Târgu Mureș.

This transition represented a coordinated effort among Romanian medical universities to align admission requirements with more rigorous international standards, ensuring that the selection process better reflects prerequisite comprehensive anatomical and physiological knowledge of all body systems, essential for first-year medical students. The examination employs multiple-choice question (MCQ) format, requiring not only content mastery, but also analytical reasoning skills to navigate complex question types.

The expanded scope and complexity of Barron's textbook may present significant challenges for prospective students, and this is the reason why beginning with the 2023-2024 academic year, our university initiated free-access preparatory courses for future candidates. These courses were intended to provide equitable access to structured learning opportunities, particularly for candidates without access to private tutoring or other preparatory programs.

The program evolved from the initial intensive format (March-May 2024), towards an in-depth approach, spanning two academic semesters (October 2024-May 2025). This extension allowed more comprehensive content delivery and additional practice. However, the effectiveness of such institutional initiatives requires a systematic evaluation beyond anecdotal impressions. Therefore, this study aimed to systematically evaluate future candidates' perception of the free preparatory course initiative at our university. Secondary objectives included characterizing participants' demographics, educational backgrounds, and entrance examination preferences, in parallel with perceived learning benefits and satisfaction levels. Understanding all these aspects is essential for evidence-based program refinement and potential replication at other higher schools of medicine.

MATERIALS AND METHODS

Preparatory Course Structure. The preparatory program offered comprehensive coverage of all 23 chapters from Barron's textbook through systematic instruction by senior experienced faculty members from the Department of Anatomy and Embryology. Recognizing visualization chal-

lenges inherent in the Barron's monochrome illustrations, instructors supplemented lectures with highly didactic color images from relevant anatomical atlases, facilitating comprehension of three-dimensional spatial relationships and complex structural features, such as saddle-type joints, which display both concavity and convexity on each contact surface.

The course also integrated structured multiple-choice question (MCQ) exercises with varying difficulty levels, training the candidates for analytical approaches to anatomical associations, multiple selections, structural exclusions, spatial relationships between anatomical structures, and image-based identification skills that are essential for a successful performance in the exam.

The preparatory course program utilized a weekly registration system managed through university enrollment forms on a first-come, first-served basis, with each enrollment form published online at the beginning of the week, for lectures held on weekends (Saturday or Sunday). Enrollment was limited to amphitheater capacity (maximum 110 participants per session) to ensure adequate instructional quality.

The program format evolved between study years. The 2023-2024 iteration employed an intensive delivery model spanning three months (March-May 2024), providing focused pre-examination preparation. Based on preliminary participant feedback, the 2024-2025 program was redesigned as an extended in-depth format spanning two academic semesters (October 2024-May 2025), allowing more gradual content delivery, enhanced opportunities for concept reinforcement, and additional practice with demonstrative MCQ assessments administered through direct instruction and Google Forms platform.

Study Design, Participants and Data Collection Instrument. This prospective observational study employed a two-year comparative design conducted during the 2023-2024 and 2024-2025 academic years at the Grigore T. Popa University of Medicine and Pharmacy Iași.

The study population comprised voluntary participants who attended the preparatory courses and completed an anonymous evaluation questionnaire, administered via Google Forms. Questionnaire submission remained open during the program duration and shortly thereafter, allowing participants to provide feedback based on their course experience. In 2024, submissions were collected from March to June, while in 2025, submissions spanned from January to May, allowing participants sufficient exposure to form informed impressions while maximizing response rate.

The instrument featured adaptive branching logic to suit different participant categories (current high school students, university graduates seeking career transition, employed professionals) and assessed multiple domains: demographic characteristics (age, citizenship), geographical domicile, entrance examination preferences (first- and second-choice program selection), time allocation patterns for examination preparation, perceived difficulty (Likert scale, 1 = "Very easy" to 5 = "Very difficult") of specific anatomical content areas (embryology, spatial relationships between structures), and overall course usefulness rated also on a 5-point Likert scale (1 = "Not useful" to 5 = "Very useful").

A total of 119 individuals completed the questionnaire (60 participants in 2024, 59 in 2025). All participants provided explicit

informed consent for anonymous data processing prior to questionnaire submission. Inclusion criteria comprised active enrollment in the preparatory course program and willingness to complete our questionnaire.

Importantly, this questionnaire design was separated from the university enrollment forms system, ensuring no linkage between enrollment forms and this study's responses. We did not collect any names, personal identification numbers, email addresses or phone numbers, encouraging candid responses and protecting participant confidentiality in compliance with EU General Data Protection Regulation (GDPR) principles.

Statistical Analysis. Data analysis employed descriptive and inferential statistics to characterize participant demographics, study behaviors, and satisfaction levels. Continuous variables were summarized using means ± standard deviation and medians, while categorical variables were expressed as frequencies and percentages. Comparative analysis between the 2024 and 2025 cohorts was performed using Student's t-test for continuous variables with normal distribution, Pearson Chi-squared test for categorical variables, and Kruskal-Wallis test for ordinal data and non-normally distributed continuous variables. Statistical significance was established at a 95% confidence interval ($p < 0.05$). Statistical computations were performed using *SPSS* software.

Ethical Considerations and Data Availability. The study adhered to ethical principles of voluntary participation, informed consent, and data anonymization. All participants provided explicit consent for anonymous data processing, with no identifiable information collected.

Complete anonymized raw data, detailed statistical analyses with correlations between certain findings, and supplementary materials with graphics (> 50 pages) are publicly accessible via Mendeley Data, a subsidiary of Elsevier (DOI: 10.17632/2y8 nyy4yyy.1), promoting transparency and enabling independent analysis and verification of findings. Reference to specific information in this repository is indicated in text as an abbreviation (MendRep, DocXX, Table YY / Figure YY) throughout the manuscript, together with corresponding reference (1).

RESULTS

Participant Demographics

The study enrolled 119 participants, distributed equally between the two cohorts: 60 participants in 2024 and 59 in 2025. The mean age was 18.96 years (SD = 3.123, range: 16-43 years), with no significant age difference between cohorts (2024: 18.82 ± 2.541 years *vs.* 2025: 19.10 ± 3.637 years; $t = -0.496$, $p = 0.621$). Nearly all participants were Romanian citizens (99.2%, n = 118), with one participant holding dual Romanian and Moldovan citizenship (MendRep, Doc05, Table 1) (1).

Medicine was the overwhelming first choice for admission (91.6%, n = 109), followed by Dental Medicine (4.2%, n = 5), Nursing (2.5%, n = 3), and Bioengineering (0.8%, n = 1). The distribution of first-choice specialization remained stable between cohorts ($\chi^2 = 2.754$, $p = 0.600$). The majority of participants (63.0%, n = 75) were currently enrolled in high school, with 42.0% in 12th grade and 20.2% in 11th grade. High school enrollment status did not differ significantly between 2024 and 2025 cohorts ($\chi^2=0.203$, $p=0.653$) (Mend Rep, Doc05, Table 2) (1).

Geographic distribution revealed that 63.0% (n = 75) of participants attended schools in Iași County, while 26.1% (n = 31) commuted from other counties to attend the preparatory courses. Participants came from diverse educational backgrounds, with 66.4% enrolled in National Colleges without specialized domains and 20.2% in Theoretical High Schools (MendRep, Doc05, Table 2) (1).

Study Habits and Exam Preparation. Participants allocated a mean of 19.99 hours weekly (SD = 11.015, range: 2-50 hours) to studying anatomy and physiology from Barron's textbook, and 9.58 hours weekly (SD = 6.774, range: 0-40 hours) to the second exam subject (MendRep, Doc05, Table 3) (1). Organic Chemistry was the most popular second exam choice (67.2%, n = 80), followed by Physics (27.7%, n = 33) (MendRep, Doc05, Table 7) (1).

A substantial proportion (33.6%, n = 40) dedicated 75-90% of their total weekly study time to UMF admission preparation, while 26.9% (n = 32) focused exclusively (100%) on entrance exam preparation (MendRep, Doc05, Table 5) (1).

Among 69 participants who took the admission simulation exam, the mean score was 6.88 ± 1.66 (range: 2.03-9.60) (MendRep, Doc05, Table 9) (1). Most students perceived this grade as reflective of their knowledge (28.6%, n = 34), while 24.4% (n = 29) felt they knew the material better than their score indicated (MendRep, Doc05, Table 10) (1).

Perceived Difficulty and Course Satisfaction. Participants were asked to rate the difficulty of selected chapters (Likert scale, 1 = very easy, 5 = very difficult), traditionally considered challenging by first-year university students. For the musculoskeletal system, ratings were predominantly moderate to high, with 42.9% (n = 51) rating it as "4" and 31.9% (n = 38) as "5" (MendRep, Doc05, Table 11) (1). The perception of difficulty did not differ significantly between the 2024 and 2025 cohorts (χ^2 = 6.019, p = 0.111) (tab. I). Cell division, gamete formation, and intrauterine development received more varied difficulty ratings, with 34.5% (n = 41) rating these chapters as "3" and 26.1% (n = 31) as "4" (MendRep, Doc05, Table 12) (1), again with no significant difference between cohorts (χ^2 = 0.191, p = 0.996) (tab. II).

TABLE I.

Perceived difficulty of the chapters on the skeletal and muscular system, by cohort year (2024 *vs.* 2025)

How difficult do you think the chapters on the skeletal and muscular system ("bones and muscles") are?		Year			
		2024		2025	
		n	%	n	%
Likert scale: 1 = very easy 3 = neutral 5 = very difficult	1	0	0%	0	0%
	2	1	1.7%	5	8.5%
	3	9	15.0%	15	25.4%
	4	27	45.0%	24	40.7%
	5	23	38.3%	15	25.4%
Total		60	100.0%	59	100.0%
Pearson Chi-square = 6.019 / p = 0.111					

TABLE II.

Perceived difficulty of the chapters on cell division, gamete formation, and intrauterine development, by cohort year (2024 *vs.* 2025)

How difficult do you think the chapters on cell division, gamete formation and intrauterine development are?		Year			
		2024		2025	
		n	%	n	%
Likert scale: 1 = very easy 3 = neutral 5 = very difficult	1	4	6.7%	3	5.1%
	2	11	18.3%	11	18.6%
	3	21	35.0%	20	33.9%
	4	15	25.0%	16	27.1%
	5	9	15.0%	9	15.3%
Total		60	100.0%	59	100.0%
Pearson Chi-square = 0.191 / p = 0.996					

Course usefulness showed a notable improvement in maximum satisfaction on the Likert scale. The combined proportion of participants rating the courses as highly useful (ratings 4 and 5) increased slightly from 80.0% in 2024 to 83.1% in 2025, though this difference did not reach statistical significance (χ^2 = 3.360, p = 0.339). Across both cohorts, 81.5% of all participants (n = 97) rated the courses as either "4" or "5" on the 5-point usefulness scale (tab. III).

TABLE III.

Perceived course satisfaction in terms of usefulness, by cohort year (2024 *vs.* 2025)

How useful do you think these free courses in human anatomy and physiology, organized by Grigore T. Popa University of Medicine and Pharmacy, are for you?		Year			
		2024		2025	
		n	%	n	%
Likert scale: 1 = not useful 3 = neutral 5 = very useful	1	0	0%	0	0%
	2	1	1.7%	1	1.7%
	3	11	18.3%	9	15.3%
	4	21	35.0%	13	22.0%
	5	27	45.0%	36	61.0%
Total		60	100.0%	59	100.0%
Pearson Chi-square = 0.191 / p = 0.996					

Importantly, the proportion of participants rating the courses as "5" (very useful) varied from 45.0% (n = 27) in 2024 to 61.0% (n = 36) in 2025, representing a 36% relative increase. Conversely, ratings of "4" decreased from 35.0% (n = 21) to 22.0% (n = 13), and ratings of "3" decreased from 18.3% (n = 11) to 15.3% (n = 9), illustrating a shift toward higher satisfaction in the extended program format (tab. III).

Correlation Analyses. We performed extensive correlation and association analyses to explore potential relationships between participant characteristics and their perceptions of course content difficulty and overall usefulness. The complete set of correlation matrices and statistical tests (Tables 19-58) is available in the supplementary data repository (MendRep, Doc05) (1).

While most demographic and behavioral variables showed no significant associations with outcome measures, four relationships emerged with statistical significance ($p < 0.05$), which we will examine in detail.

No significant relationship was found between age and the following: (a) difficulty of the chapters on the skeletal and muscular system (Kruskal-Wallis H = 2.204, p = 0.531), (b) difficulty of the chapters on cell division, gamete formation, and intrauterine development (Kruskal-Wallis H = 6.281, p = 0.179), and (c) course usefulness ratings (Kruskal-Wallis H = 0.694, p = 0.875), suggesting that our preparatory lectures were equally beneficial across different age groups (MendRep, Doc05, Table 19) (1).

Similarly, current high school enrollment status did not significantly affect perceptions of course usefulness (χ^2 = 2.860, p = 0.414) (MendRep, Doc05, Table 25) (1). The number of weekly study hours allocated to anatomy did not significantly correlate with perceived difficulty of the musculoskeletal system (Kruskal-Wallis H = 4.979, p = 0.173) (MendRep, Doc05, Table 32) (1) or of the chapters on cell division, gamete formation, and intrauterine development (Kruskal-Wallis H = 1.537, p = 0.820) (MendRep, Doc05, Table 33) (1).

In contrast, four variables demonstrated statistically significant associations with either perceived content difficulty or course usefulness ratings.

First finding refers to how current high school students rated cell division and embryology topics as more difficult compared to graduates (χ^2 = 10.738, p = 0.030), with a higher proportion rating them as 4 or 5 (41.4% *vs.* 40.9% combined for 4+5), but notably fewer rating them as "very easy" (1.3% *vs.* 13.6%) (tab. IV).

TABLE IV.

Perceived difficulty of cell division, gamete formation, and intrauterine development chapters by current high school enrollment status

How difficult do you think the chapters on cell division, gamete formation and intrauterine development are?		Do you currently attend a high school?			
		Yes		Not	
		n	%	n	%
Likert scale: 1 = very easy 3 = neutral 5 = very difficult	1	1	1.3%	6	13.6%
	2	16	21.3%	6	13.6%
	3	27	36.0%	14	31.8%
	4	17	22.7%	14	31.8%
	5	14	18.7%	4	9.1%
Total		75	100.0%	44	100.0%
Pearson Chi-square = 10.738 / p = 0.030*					

Secondly, high school specialization significantly influenced perceived difficulty of the chapters on cell division, gamete formation, and intrauterine development (χ^2 = 28.915, p = 0.025) (tab. V), whereas no significant association was found with perceived difficulty of the musculoskeletal system chapters (χ^2 = 14.374, p = 0.277) (MendRep, Doc05, Table 29) (1). Thus, high school students from Natural Sciences profiles rated embryology content as relatively easier, with 28.6% finding it "Easy" (rating 2) compared to other specializations (tab. V).

TABLE V.

Perceived difficulty of cell division, gamete formation, and intrauterine development chapters by high school specialization

How difficult do you think the chapters on cell division, gamete formation and intrauterine development are?		What profile/specialization do you follow in high school?									
		Another specialization that is not found above		Mathematics - Computer Science		Human Profile - Philology		Vocational profile		Natural Sciences	
		n	%	n	%	n	%	n	%	n	%
Likert scale: 1 = very easy 3 = neutral 5 = very difficult	1							1	25.0%		
	2			4	16.0%	1	12.5%	1	25.0%	10	28.6%
	3			9	36.0%	4	50.0%	2	50.0%	12	34.3%
	4	1	33.3%	8	32.0%	1	12.5%			7	20.0%
	5	2	66.7%	4	16.0%	2	25.0%			6	17.1%
Total		3	100.0%	25	100.0%	8	100.0%	4	100.0%	35	100.0%
Pearson Chi-square = 28.915 / p = 0.025*											

Thirdly, prior exposure to school-based or biology-teacher-led preparatory sessions significantly influenced our university course usefulness ratings (χ^2 = 18.793, p < 0.001) (tab. VI), though notably, only a small percentage of participants (11.0%, n = 8 of 73 current 11th-12th graders) had access to such sessions at their schools. Among this limited group with prior preparatory experience, 25.0% rated the courses as "Not very useful" (rating 2), while 62.5% rated them as "Very useful" (rating 5). In contrast, among high school pupils without prior preparatory session experience (n = 65), none gave the first-lowest or the second-lowest rating, 21.5% rated the courses neutrally (rating 3), and a great majority rated them "Useful" (27.7%) and "Very useful" (50.8%) (tab. VI).

TABLE VI.

Perceived course usefulness by prior exposure to school-based or biology-teacher-led preparatory sessions

How useful do you think these free courses in human anatomy and physiology, organized by Grigore T. Popa University of Medicine and Pharmacy Iasi, are for you?		If you are in the 11th or 12th Grade, is your school (or your biology teacher) organizing a weekly preparation / class with the subjects from Barons?			
		Yes		Not	
		n	%	n	%
Likert scale: 1 = not useful 3 = neutral 5 = very useful	1	0	0%	0	0%
	2	2	25.0%	0	0%
	3	0	0%	14	21.5%
	4	1	12.5%	18	27.7%
	5	5	62.5%	33	50.8%
Total		8	100.0%	65	100.0%
Pearson Chi-square = 18.793 / p < 0.001**					

Lastly, commute distance significantly influenced course usefulness ratings (χ^2 = 14.203, p = 0.027). Participants commuting from other counties rated the courses as "Very useful" (rating 5) at notably higher rates (71.0%) compared to those living in Iasi Municipality (48.8%) (tab. VII).

TABLE VII.

Perceived course usefulness by commute distance to our university

How useful do you think these free courses in human anatomy and physiology, organized by Grigore T. Popa University of Medicine and Pharmacy Iasi, are for you?		Do you have to commute to participate in the admission preparation courses organized by Grigore T. Popa University of Medicine and Pharmacy Iasi?					
		Yes, I live in another county		Yes, I live in Iasi County, but at a distance of more than 15 km from Iasi		No, I live in the Municipality of Iasi (including the surrounding areas)	
		n	%	n	%	n	%
Likert scale: 1 = not useful 3 = neutral 5 = very useful	1	0	0%	0	0%	0	0%
	2	0	0%	0	0%	2	2.4%
	3	4	12.9%	0	0%	16	19.5%
	4	5	16.1%	5	83.3%	24	29.3%
	5	22	71.0%	1	16.7%	40	48.8%
Total		31	100.0%	6	100.0%	82	100.0%
Pearson Chi-square = 14.203 / p = 0.027*							

DISCUSSION

In the Romanian exam-based medical school admission systems, high-stakes standardized testing can create unique challenges for prospective students, particularly those from underserved communities or regions with limited access to high-quality preparatory resources (2, 3). Free, university-led preparatory initiatives address these aspects by providing equitable access to structured exam preparation and ensuring that admission success reflects academic potential rather than socioeconomic advantage (4).

This study examined the perceptions and learning experiences (tabs. I, II) of participants in free preparatory courses for the Grigore T. Popa University of Medicine and Pharmacy Iași entrance examination across two consecutive academic years (2024 and 2025). Participant demographics reflected the typical profile of prospective medical students, with a mean age of 18.96 years (range 16-43), predominantly comprised of current high school students (63.0%) and Romanian citizens (99.2%). The majority selected General Medicine as their first choice (91.6%), and demonstrated substantial commitment to entrance exam preparation, with 89.1% dedicating over half of their total study time to anatomy and physiology (MendRep, Doc05, Tables 1, 2, 5) (1).

Understanding student perspectives on educational interventions is fundamental to evidence-based program development and refinement, as participant experiences directly inform pedagogical effectiveness and institutional decision-making (5-7).

Our findings reveal consistently high

satisfaction with the preparatory courses, with notable improvements in perceived usefulness from 2024 to 2025 (tab. III), alongside significant correlations between demographic and educational variables and both perceived difficulty of exam content and course usefulness ratings.

Current high school students rated the topics on cell division, gamete formation, and intrauterine development as significantly more difficult compared to responders who finished high school ($\chi^2 = 10.738$, $p = 0.030$) (tab. IV). While both groups showed similar proportions rating this content as difficult or very difficult (ratings 4+5: 41.4% *vs.* 40.9%), responders who had already finished high school were significantly more likely to rate it as "very easy" (13.6% *vs.* 1.3%), suggesting that their additional educational experience or cognitive maturation facilitated comprehension of these embryology topics. Moreover, high school specialization significantly influenced these difficulty perceptions ($\chi^2 = 28.915$, $p = 0.025$) (tab. V), with students from Natural Sciences profiles rating this content as relatively easier - 28.6% finding it "easy" (rating 2) compared to other specializations. In contrast, Mathematics-Computer Science and Humanities students showed more varied difficulty perceptions, suggesting that prior exposure to biological concepts in Natural Sciences curricula provided foundational knowledge that facilitated comprehension of embryology topics.

The significant association between prior preparatory experience and our program usefulness ratings ($\chi^2 = 18.793$, $p < 0.001$) revealed a notable pattern (tab. VI). Participants with a comparative framework for evaluating preparatory instruction, having experienced similar classes at their high schools, were better positioned to assess the quality and pedagogical value of the university-level courses, despite representing only 11.0% of current high school participants. While a quarter of this small group evaluated the courses more critically, their great majority (75%) provided validation of our program quality. Moreover, we observed that only a small fraction of high school pupils has access to school-based preparatory sessions, emphasizing the critical importance of university-led initiatives in providing equitable access to high-quality exam preparation (tab. VI).

Commute distance correlated significantly with course usefulness ratings ($\chi^2 = 14.203$, $p = 0.027$) (tab. VII). Participants who invested greater time and effort to commute from other counties valued the program more highly, potentially reflecting both self-selection of highly motivated individuals and tangible appreciation for educational access that would otherwise be unavailable in their home regions.

The observed relative increase of 36%, in participant satisfaction rating the courses as "5" (very useful), from 45.0 % to 61.0% between its first two years of implementation, likely reflects the program's evidence-based evolution. Our preparatory program evolved significantly from the initial 2024 intensive format (March-May 2024) to the 2024-2025 approach over two academic semesters (October 2024-May 2025), thus achieving a thorough curriculum coverage. The extension decision was taken by our university, based on the preliminary feedback and pedagogical considerations (MendRep, Doc03) (1).

The transition from intensive to extend-

ed format required both organizational commitment and faculty members mobilization, but the demonstrated improvements in participant satisfaction validated its success. The program's sustainability is evidenced by the continuation of this extended format for the new academic year of 2025-2026, with the first lecture for the 2026 admission exam being delivered in October 2025.

Future program development could address the current curricular gap by incorporating physics courses alongside the existing human anatomy and physiology, and organic chemistry preparation modules, thereby supporting the minority of candidates who select physics instead of organic chemistry as their second examination subject at the Faculties of Medicine and Dental Medicine. Another pathway for program expansion would be increasing participant capacity through technology-enhanced delivery methods, such as simultaneous audio-visual transmission to nearby dual amphitheaters. This approach would preserve in-person interactive instruction with the teacher during breaks and at the end of the lecture, a pedagogical approach long recognized as beneficial for student outcomes (8).

Several limitations of our research warrant consideration. First, the fully anonymous questionnaire design, while essential for protecting participant confidentiality and encouraging candid responses, precluded technical prevention of duplicate submissions. Although appeals to honesty were made to minimize duplicate responses, the anonymous nature of data collection made verification of unique respondents impossible. However, given the educational context, voluntary participation, and absence of incentives for multiple submissions, we assume the potential for duplicate responses to be minimal and unlikely to substantially alter the study's primary findings. This trade-off between anonymity and duplicate prevention represents an inherent methodological constraint in anonymous survey research that prioritizes participant privacy (9).

CONCLUSIONS

The highly positive feedback from participants validated the preparatory program's effectiveness and triggered informed evidence-based expansion from an intensive format to an in-depth material presentation; further expansion could include physics preparation to support the minority of candidates who select this as their second examination subject.

Anonymous questionnaires proved valuable tools for capturing multiple dimensions of participants' perception regarding study effort and commitment.

Our university pre-admission training initiative reflects institutional responsiveness to learner needs and provides a replicable model for other medical universities in Romania where competitive entrance examinations are in place.

The participation of future candidates from other counties demonstrates the program's regional reach and its value for supporting exam preparation across an extended geographical area.

ACKNOWLEDGMENTS

Preliminary findings from the 2024 cohort (n = 60), without advanced correlative statistical analysis, were presented orally at the XXIII National Congress of the Romanian Society of Anatomy, Oradea, Roma-

nia, March 20-22, 2025, under the title "Positive Perception and Characterization of the Learning Effort of the Participants in the Free Preparatory Courses for the Admission Exam in 2024 Organized by Grigore T. Popa University of Medicine and Pharmacy Iași" by the first author of this manuscript.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no funding for this study.

TROSPIUM CHLORIDE *VERSUS* TAMSULOSIN IN THE TREATMENT OF DOUBLE-J STENT RELATED LOWER URINARY TRACT SYMPTOMS (LUTS): A CASE-CONTROL STUDY (Abstract): Double-J ureteral stents frequently cause lower urinary tract symptoms (LUTS), including urinary urgency and pollakiuria, which significantly affect patient comfort. This study compared the efficacy and safety of trospium chloride versus tamsulosin in patients with stent-related LUTS. **Materials and methods:** We conducted a retrospective 6-year study comparing patients with LUTS in the presence of double-J stents who had received trospium for 4 weeks (39 patients) with patients who had received tamsulosin (52 patients). **Results:** Both trospium and tamsulosin relieved LUTS symptoms ($p<0.05$). Trospium relieved pollakiuria (82.05% *vs.* 61.53%, $p=0.034$) and urinary urgency (87.17% *vs.* 59.61%, $p=0.003$) in a higher percentage than tamsulosin. However, there was no statistically significant difference in the improvement of urinary urgency incontinence (80% *vs.* 47.05%, not significant at $p<0.05$), hypogastric pain (64% *vs.* 40%, $p=0.103$), foreign body sensation (64.28% *vs.* 38.09%, $p=0.128$) and macroscopic hematuria (37.5% *vs.* 18.18%, not significant at $p < 0.05$); side effects occurred rarely, with no statistically significant difference between the two groups (5.12% *vs.* 5.76%, not significant at $p<0.05$). **Conclusions:** Trospium chloride is a safe and effective option for managing LUTS associated with double-J stents and provides superior improvement in pollakiuria and urinary urgency compared with tamsulosin. **Keywords:** TROSPIUM CHLORIDE, TAMSULOSIN, DOUBLE-J STENT, LOWER URINARY TRACT SYMPTOMS, LUTS, STENT-RELATED SYMPTOMS.

INTRODUCTION

Trospium chloride is a quaternary ammonium derivative of nortropanol (1), a competitive cholinergic receptor antagonist (2). Its activity is predominantly peripheral, non-selective antimuscarinic, and it has no effects on the central nervous system (3). Trospium is commonly used for overactive bladder to relieve urinary incontinence associated with urinary urgency and pollakiuria (4). It is also used to relieve these symptoms in neurogenic detrusor overactivity (5) and to reduce postoperative bladder irritation and radiation-induced cystitis (6). Trospium is an anticholinergic agent that has been used in Europe since the 1990s and in the USA since 2004 (7). Over the past 30 years of experience, only a few

side effects have been reported, the most common being dry mouth, constipation, and headache (8, 9). This safety profile has been confirmed in studies involving more than 10,000 patients (1). Trospium can be administered orally in one or more doses not exceeding 45-60 mg per day (9-11).

Urinary catheters or stents are commonly used in clinical practice, and many patients wear them for weeks, months, or even years (12). The presence of these catheters predisposes patients to urinary tract infections (13, 14), hematuria, pollakiuria, urinary urgency, and urge incontinence (15, 16). They relax the smooth muscle fibers of the bladder neck and the prostate, which leads to lower micturition pressure and urinary reflux (17). The effect can be measured by urodynamic studies, which have shown normalization of intravesical pressure and increased cystometric bladder capacity (18). Several drugs have been proposed to treat these symptoms, including tamsulosin, silodosin, or their combination (19, 20). Tamsulosin is an alpha-blocker used not only to treat LUTS associated with benign prostatic hyperplasia (BPH), but also to promote the passage of ureteral stones or fragments formed during extracorporeal lithotripsy and to treat symptoms associated with double-J catheters (21). However, both tamsulosin and solifenacin have certain side effects, such as arterial hypotension and retrograde ejaculation in the case of tamsulosin, and central nervous system effects-particularly in the elderly-in the case of solifenacin (22, 23).

As trospium chloride is the only antimuscarinic drug that has no effects on the central nervous system (22) and lacks the adverse effects associated with tamsulosin (orthostatic hypotension, retrograde ejaculation), we aimed to determine whether it could be a viable alternative for the treatment of secondary LUTS in double-J stent carriers. To our knowledge, this is the first study in the literature to evaluate the efficacy and safety of trospium in this specific patient group.

MATERIALS AND METHODS

Study Population and Design. We conducted a retrospective case-control study of patients with double-J ureteral stents who underwent Extracorporeal Shock Wave Lithotripsy (ESWL) at Elytis Hospital between 1 January 2018 and 31 December 2024. Of the total number of urological patients admitted, 289 had double-J stents. Among these, 42.56% (123 patients) presented with bladder symptoms related to the presence of the double-J stents. All patients had only one double-J stent inserted. These patients were eligible for inclusion in the study. The study was approved by the Ethics Committee of Elytis Hospital (Protocol No. 3927/07.05.2025).

Patients with LUTS who also had benign prostatic hyperplasia (3 patients), those who received tamsulosin in combination with solifenacin or other drugs for LUTS due to the presence of double-J stents (6 patients), those who developed urinary tract infections during treatment (2 patients), and patients with incomplete data in hospital records (21 patients) were excluded. In all patients, urine culture was performed, to exclude urinary tract infection, a well-known complication of double-J stents, even with multidrug-resistant bacteria (24).

Study Procedure. The study group consisted of patients with LUTS and double-J stents who were administered trospium chloride (Inkontan™, Montavit, Austria), and the control group consisted of patients with LUTS and double-J stents

who were administered tamsulosin (Fokusin™, Zentiva, Czech Republic). The indication for treatment with tamsulosin was the presence of symptoms secondary to the double-J stents, as well as to promote the elimination of lithiasis fragments smaller than 4 mm occurring after ESWL.

Trospium chloride was administered at a dose of 15 mg twice daily (morning and evening), and tamsulosin was administered 0.4 mg once daily in the evening. No patient received 15 mg of trospium three times daily, so the maximum recommended dose of 45 mg per day was not reached, in order to avoid known anticholinergic side effects.

Patients who underwent ESWL and had LUTS started treatment three days after the procedure. During this period, they completed a voiding calendar to assess the severity of pollakiuria. Treatment with trospium or tamsulosin lasted four weeks, after which patients returned for follow-up. Before each new ESWL session and follow-up, an ultrasound scan and X-ray of the kidneys were performed to detect calcifications or misplacement of the double-J catheters, especially at the distal intravesical end, as these could influence treatment response and represent potential bias.

The ureteral catheters were made of polyurethane, 6-7 Ch thick and 24-28 cm long, adjusted to the individual patient height and according to the manufacturer specifications. The length of the distal end in the bladder was not measured, but all patients had a complete distal loop of the double-J stent in the bladder.

Patient Assessment and Outcome Measurement. The following variables were collected from hospital records: age, gender, history of urinary tract infections, underlying condition requiring stent insertion, right-left localization of the double-J catheter, and comorbidities potentially influencing LUTS, such as diabetes and neurological disorders. In both groups, the drug dose, administration frequency, and treatment duration were analyzed. The presence of hematuria, pollakiuria, urinary urgency and urge incontinence, intravesical foreign body sensation, and hypogastric pain (bladder tension or persistent pain) were recorded.

Visual Analog Scale (VAS) questionnaires for pain were not used, as facial expression was considered subjective and patients generally requested removal of the stent if discomfort was significant. Therefore, all included patients were presumed to have moderate pain. To assess the reduction in daily micturitions, a voiding calendar was used for three consecutive days before and at the end of treatment. Treatment discontinuation due to side effects or lack of efficacy was also recorded.

All patients were evaluated and managed by the same two attending urologists, who followed identical departmental protocols for the treatment of double-J stent-related symptoms. Tamsulosin was prescribed primarily to relieve stent-related LUTS and to facilitate the passage of residual stone fragments <4 mm after ESWL, whereas trospium chloride was preferentially used in patients whose predominant symptoms were urinary urgency and frequency without the need for expulsive therapy. Baseline symptom presence was similar across groups.

Patients with LUTS following ESWL were treated for one month with either trospium or tamsulosin and then re-evaluated. The presence of symptoms and subjective improvement were recorded at baseline and after one month of therapy.

The micturition calendar was reviewed during the control visit.

Statistical Analysis. Quantitative variables were described by mean and standard deviation, and qualitative variables by percentages. Quantitative variables were compared using the t-test for normally distributed data and the Mann-Whitney U-test for non-normally distributed data. Normality of data distribution was verified using the Kolmogorov-Smirnov test. Qualitative variables were compared using the chi-square test or Fisher's exact test when fewer than five observations were present. Statistical significance was considered at $p < 0.05$. Data were processed using *Microsoft Excel version 2019* (Microsoft, Redmond, WA, USA) and *SPSS version 24.0* (IBM, Chicago, IL, USA).

RESULTS

During the study period, a total of 91 patients underwent ESWL and experienced LUTS due to the presence of double-J stents. Of these, 39 patients received trospium chloride (study group) and 52 patients received tamsulosin (control group).

Demographic and Clinical Characteristics

First table presents the demographic and clinical characteristics of patients in both groups.

There were no statistically significant differences in age, sex, laterality of the stent, stone location, or comorbidities such as diabetes or obesity between the two groups. No patient had neurological disorders that could have influenced LUTS or treatment response.

TABLE I.
Demographic and Clinical Characteristics of Patients in the Trospium and Tamsulosin Groups

Characteristic	Trospium Group (n = 39)	Tamsulosin Group (n = 52)	p-value	Test
Age (years, mean ± SD)	48.85 ± 14.12	47.69 ± 11.94	0.677	Student's *t*-test
Sex (Male/Female), n (%)	15 / 24 (38.5% / 61.5%)	22 / 30 (42.3% / 57.7%)	0.877	Chi-square
Indication for stent insertion				
Infected hydronephrosis, n (%)	34 (87.2%)	44 (84.6%)	0.729	Chi-square
Recurrent renal colic, n (%)	5 (12.8%)	8 (15.4%)	0.729	Chi-square
Stent laterality				
Right ureter, n (%)	17 (43.6%)	26 (50.0%)	0.544	Chi-square
Left ureter, n (%)	22 (56.4%)	26 (50.0%)	0.544	Chi-square
Stone location (pre-ESWL)				
Ureteral calculus, n (%)	23 (59.0%)	34 (65.4%)	0.531	Chi-square
Pyelocaliceal calculus, n (%)	16 (41.0%)	18 (34.6%)	0.531	Chi-square
Comorbidities				
Diabetes mellitus, n (%)	2 (5.1%)	3 (5.8%)	N.S.	Fisher's exact
Obesity (BMI > 30), n (%)	4 (10.3%)	5 (9.6%)	N.S.	Fisher's exact

N.S.-non-significant

There were no statistically significant differences in age, sex, laterality of the stent, stone location, or comorbidities such as diabetes or obesity between the two groups. No patient had neurological disorders that could have influenced LUTS or treatment response.

Baseline Symptoms

In the second table are presented the baseline prevalence of stent-related LUTS prior to treatment.

TABLE II.

Baseline Prevalence of Stent-Related Lower Urinary Tract Symptoms in Each Group (Pre-Treatment)

Symptom	Trospium Group (n = 39)	Tamsulosin Group (n = 52)	p-value	Test
Urinary urgency, n (%)	39 (100%)	52 (100%)	N/A	—
Urge urinary incontinence, n (%)	10 (25.6%)	17 (32.7%)	0.619	Chi-square
Urinary frequency (pollakiuria), n (%)	39 (100%)	52 (100%)	N/A	—
Voids per day (mean ± SD)	13.55 ± 4.31	13.45 ± 3.88	0.771	Mann-Whitney U
Suprapubic (hypogastric) pain, n (%)	25 (64.1%)	35 (67.3%)	0.749	Chi-square
Intravesical foreign body sensation, n (%)	14 (35.9%)	21 (40.4%)	0.663	Chi-square
Gross hematuria, n (%)	8 (20.5%)	11 (21.2%)	0.940	Chi-square

The frequency of the six symptoms recorded in the study was similar in both groups, with no statistically significant differences between the groups. We found that the only symptoms that occurred in all patients in both groups were pollakiuria and urinary urgency. There were no differences between the two groups in the total number of micturitions per day. The other symptoms occurred in much smaller percentages, namely urge urinary incontinence and hematuria, which occurred in about a quarter of patients in both groups.

Symptom Improvement After Four Weeks

Table III summarizes symptom improvement after four weeks of treatment.

TABLE III.

Patients Reporting Improvement of Symptoms After 4 Weeks of Treatment

Symptom	Trospium Improved n/N (%)	Tamsulosin Improved n/N (%)	p-value	Test
Urinary urgency	34/39 (87.2%)	31/52 (59.6%)	0.003	Chi-square
Urge urinary incontinence	8/10 (80.0%)	8/17 (47.1%)	N.S.	Fisher's exact
Urinary frequency (pollakiuria)	32/39 (82.1%)	32/52 (61.5%)	0.034	Chi-square
Suprapubic pain	16/25 (64.0%)	14/35 (40.0%)	0.103	Fisher's exact
Intravesical foreign body sensation	9/14 (64.3%)	8/21 (38.1%)	0.128	Fisher's exact
Gross hematuria	3/8 (37.5%)	2/11 (18.2%)	N.S.	Fisher's exact

N.S.-non-significant

In the study group, only pollakiuria, urinary urgency and urge incontinence improved by more than 80%, while macroscopic hematuria, hypogastric pain and foreign body sensation improved in more than 60% of patients. In the control group, on the other hand, the percentage of patients reporting an improvement in symptoms was significantly lower than in the study group, with only pollakiuria and the percentage of improvement of more than 50% was achieved. For urge incontinence, hypogastric pain and intravesical foreign body sensation, the percentage was less than 50%, and for macroscopic hematuria even less than 20%. However, statistically significant differences were found only for pollakiuria (p = 0.03) and urinary urgency (p = 0.003).

For urge incontinence, hypogastric pain, foreign body sensation and hematuria, there was no statistically significant difference in the number of patients who reported an improvement in these symptoms, while the total percentage of patients who subjectively reported an improvement showed a statistically significant difference in favor of the group receiving Trospium 30mg/day.

The mean number of micturitions/day calculated from the micturition calendar before treatment and at the end of treatment was significantly reduced in both the study group (13.68 ± 4.08 *vs.* 10.43 ± 5.28, p<0.001) (Wilcoxon test) and the control group (13.67 ± 3.87 *vs.* 11.08 ± 5.08, p<0.001) (Wilcoxon test).

Adverse Events

Treatment-related side effects are presented in the fourth table.

TABLE IV.

Treatment-Related Adverse Events Reported in Each Group

Adverse Event	Trospium Group (n = 39)	Tamsulosin Group (n = 52)	p-value	Test
Dry mouth	1 (2.6%)	0 (0%)	N.S.	Fisher's exact
Constipation	0 (0%)	0 (0%)	N/A	—
Dizziness (lightheadedness)	0 (0%)	3 (5.8%)	N.S.	Fisher's exact
Diarrhea	1 (2.6%)	0 (0%)	N.S.	Fisher's exact
Total side effects	**2 (5.1%)**	**3 (5.8%)**	N.S.	Fisher's exact

N.S.-non-significant

The incidence of side effects was low in both groups, with no statistically significant differences. Despite the occurrence of these side effects, this did not lead to discontinuation of treatment by the patients, with the exception of one patient with diarrhea in the study group who discontinued treatment after 10 days. We note that in the control group, no patient reported constipation and only one patient reported dry mouth, which are recognized side effects of parasympathomimetic. In the control group, a small number of patients reported dizziness. Although retrograde ejaculation is a common complication in male patients, we did not investigate its occurrence due to the mixed-sex group. However, no patient discontinued tamsulosin treatment due to the presence of this side effect.

DISCUSSION

To our knowledge, this is the first

study to evaluate the efficacy and safety of trospium chloride in patients with LUTS due to double-J stents. We found that trospium demonstrated superior efficacy compared to tamsulosin in the treatment of pollakiuria and urinary urgency, with both drugs being well tolerated and associated with a low rate of side effects.

The demographic characteristics of patients were similar between groups in terms of age, sex, stent laterality, and stone location. The mean age of participants was consistent with other studies investigating trospium (25, 26), typically ranging between 45 and 60 years. Equal distribution of diabetic patients and the absence of neurogenic bladder disorders minimized confounding factors affecting LUTS or drug response. We included only patients with lithiasis and double-J stents, excluding those with other causes of LUTS such as radiotherapy or urinary tract infections, to further reduce bias.

Although most studies investigating trospium for overactive bladder used doses of 40-60 mg/day (27, 28), in our study we administered 30 mg/day in two doses to minimize side effects. Increasing the dose to 45 mg/day might have enhanced efficacy, as previous reports suggest 40 mg/day as optimal for balancing efficacy and tolerability (30), with potential additional benefits at 60 mg/day (30). Trospium is known for good safety even in elderly patients with dementia or Parkinson's disease (22, 25), although such patients were not included in our analysis.

In the literature, only one study has assessed trospium for catheter-related LUTS, specifically in patients with Foley urethral catheters (12), but none have focused on double-J stents. Similar to other investigations (12, 19, 27, 28), we evaluated improvement in individual symptoms rather than overall pain or quality-of-life scores (20, 29), allowing a clearer understanding of specific drug effects.

All patients continued therapy, except one in the trospium group who discontinued due to diarrhea. The discontinuation rate for trospium is reported to be lower than for other anti-muscarinics (31).

Our findings showed significantly greater improvement in pollakiuria and urinary urgency with trospium compared to tamsulosin. Pollakiuria improved by an average of 3.19 micturitions per day, consistent with previous studies (9), and higher than those reporting a reduction of fewer than two micturition per day (19). The proportion of patients reporting improvement (> 80%) was greater than in other studies (approximately 62%) (27). Because we assessed total daily micturition, we could not differentiate between day and night improvements; other research indicates greater benefit during daytime (28). We defined pollakiuria as ≥ 10 micturitions per 24 hours, compared with thresholds of > 8 (19, 27) or even > 30 (32) used elsewhere. Clinically, patients with <10 micturitions per day often did not require therapy, while those exceeding 30 generally needed stent removal rather than medication.

Urinary urgency improved in both groups but more markedly with trospium (87.17% *vs.* 59.61%). This difference of nearly 30% highlights trospium's superior efficacy. Comparable benefits have been reported in other studies examining trospium for overactive bladder (5, 9, 25).

For urge urinary incontinence, the improvement was greater with trospium, though not statistically significant, likely

due to the small number of affected patients. We did not count daily incontinence episodes as in some trials (9) but relied on subjective reporting, since patient self-monitoring of these episodes is often unreliable.

Hypogastric pain and intravesical foreign body sensation improved less than pollakiuria and urgency in both groups, possibly reflecting subjective variability in symptom perception. Some patients may have expected complete symptom resolution, while others reported satisfaction with partial relief. Similar findings have been observed in studies of Foley catheter users (12).

Hematuria showed the least improvement, with no difference between groups. This likely reflects mechanical irritation from the stent, which persists despite pharmacologic relaxation of bladder smooth muscle. No cases of clot-forming hematuria occurred, and this symptom did not lead to treatment discontinuation.

Adverse effects were mild in both groups. In the trospium group, one case each of dry mouth and diarrhea was reported, with no constipation, neurological impairment, or other systemic symptoms, consistent with the literature (5, 26). No sedation or sleep disturbances occurred (33). In the tamsulosin group, dizziness was reported in a few cases, likely secondary to orthostatic hypotension. Retrograde ejaculation, although a known adverse event, was not investigated due to the mixed-sex population, but no patient discontinued tamsulosin therapy due to such complication.

Overall, trospium chloride demonstrated superior efficacy to tamsulosin in reducing urinary urgency and frequency among double-J stent carriers, with similar tolerability and safety.

This study has some limitations. First, its retrospective design inherently restricts the ability to control for potential confounding variables, including treatment selection bias arising from routine clinical prescribing patterns rather than random allocation. Second, symptom assessment relied on patient-reported improvement without the use of standardized instruments such as the USSQ, which were not validated in Romanian language at the time of patient's admission. Only pollakiuria could be quantified objectively through the three-day voiding calendar.

CONCLUSIONS

Trospium chloride showed superior efficacy compared to tamsulosin in the treatment of pollakiuria and urinary urgency among patients with double-J stents. It demonstrated similar efficacy to tamsulosin in relieving urinary urge incontinence, intravesical foreign body sensation, hypogastric pain, and hematuria. Adverse effects were rare and did not significantly increase the rate of treatment discontinuation.

Overall, trospium chloride represents a safe and effective therapeutic option for managing LUTS associated with double-J stents. Prospective studies with larger patient populations are needed to validate these findings and to better define the role of trospium chloride in the pharmacologic management of stent-related urinary symptoms.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflict of interest and no financial support was received for perfecting this article.

SELLAR AND PARASELLAR MENINGIOMAS - CLINICOPATHOLOGICAL FEATURES AND IMMUNOHISTOCHEMICAL PREDICTORS OF TUMOR GRADE. INSIGHTS FROM A RETROSPECTIVE CASE SERIES (Abstract): Sellar and parasellar meningiomas (spMs) represent a rare but clinically challenging subgroup of intracranial tumors due to their proximity to critical neurovascular and endocrine structures. This study **aimed** to provide a comprehensive clinicopathological and statistical evaluation of spMs, with particular emphasis on biological markers associated with tumor aggressiveness. **Materials and methods**: We retrospectively analyzed 15 patients with histologically confirmed spMs treated surgically at Prof. Dr. N. Oblu Emergency Clinical Hospital, Iași, between 2021 and 2025. Demographical, clinical, radiological, surgical, and immunohistochemical data [Ki-67 labeling index (Ki67 LI), progesterone receptor (PR), and p53 expression] were evaluated. Statistical analysis included comparative tests and logistic regression modeling for predictors of WHO grade. **Results:** The cohort showed a marked female predominance (80%), with a mean age of 60.3 ± 13.2 years. Most tumors originated in the sellar region (66.7%). Gross total resection was achieved in 66.7% of cases. Histopathologically, WHO grade 1 spMs predominated (73.3%), while grade 2 spMs accounted for 26.7%. Ki-67 LI values were significantly higher in grade 2 tumors (12.0 ± 2.2 vs. 3.4 ± 1.3; p=0.003), whereas PR expression was significantly reduced (42.5 ± 18.9 vs. 81.4 ± 14.8; p=0.010). Logistic regression identified Ki-67 LI (OR=1.85) as an independent risk factor and PR (OR=0.92) as a protective factor for higher tumor grade. **Conclusions**: These findings highlight the central role of tumor biology in sellar and parasellar meningiomas. Ki-67 LI and PR expression represent complementary and clinically relevant biomarkers that improve risk stratification and may guide surgical and postoperative management. **Keywords**: SELLAR MENINGIOMA, KI-67, PROGESTERONE RECEPTOR, TUMOR GRADE, PREDICTIVE BIOMARKERS.

INTRODUCTION

Meningiomas are the most frequent primary intracranial tumors in adults, representing 36-41% of these (1, 2). Intracranial meningiomas are currently classified according to the 2021 World Health Organization (WHO) Classification of Central Nervous System Tumors into grades 1–3,

based on histopathological criteria and selected molecular alterations (3). Although most meningiomas are WHO grade 1 tumor, a clinically relevant subset shows atypical or aggressive behavior, with increased recurrence risk and need for closer postoperative surveillance (3-5). Morphological grading of meningiomas does not always reflect the actual biological behavior, which is why immunohistochemical biomarkers become essential in prognostic stratification (6).

Ki-67/MIB-1 is widely used as a proliferation marker and has repeatedly been associated with higher grade, increased recurrence risk and more aggressive biological behavior (7-9).

Progesterone receptor (PR) expression, in contrast, is generally associated with more differentiated tumor biology and more favorable behavior, whereas reduced or absent PR expression is more frequently observed in higher-grade meningiomas (10).

One small group of intracranial meningiomas are the sellar and parasellar meningiomas (spMs) that may develop from arachnoid cap cell located on the level of the tuberculum sellae, planum sphenoidale, anterior or clinoid processes, sphenoid wing, cavernous sinuses, petroclival region, diaphragm sellae, or clivus (11).

SpMs represent a particularly challenging subgroup of skull base tumors because of their close anatomical relationship with the optic apparatus, pituitary region, cavernous sinus, internal carotid artery and anterior skull base structures (12). On the other hand, these tumors are quite rare, representing approximately 1%-2% of sellar lesions, but are the second most common sellar tumor after pituitary adenomas (13, 14).

In these locations, surgical management must balance maximal tumor removal with preservation of visual, endocrine and neurovascular function (15-17).

However, spMs are increasingly understood as heterogeneous tumors due to their anatomical origin heterogeneity, clinical variability and sometimes coexistence with other tumors, such as pituitary adenoma (18) or sellar Rathke cleft cyst (19).

The aim of this study was to perform a comprehensive clinicopathological and statistical analysis of a consecutive institutional series of sellar and parasellar meningiomas, with particular focus on tumor biology, as there are only few data on this issue in literature as far as we know.

MATERIALS AND METHODS

We retrospectively identified 15 patients with histologically confirmed sellar and parasellar meningiomas that were surgically treated in Neurosurgical Clinics, Prof. Dr. N. Oblu Emergency Clinical Hospital, Iasi, Romania, in a period of 5 years (January 1, 2021 – December, 31, 2025).

The following demographic, clinical and radiological data were retrospectively extracted from the electronic observation sheets located in the hospital electronic archive: patients' age and gender, tumor localization, meningioma histological subtype, immunohistochemical assessment of Ki67 Labeling Index (Ki67 LI), p53 and Progesterone Receptor (PR) expression, grade of malignancy according to WHO Classification 2021, 5th Edition, type of surgical approach, and extent of tumor resection.

The data was analyzed using *SPSS Statistics version 27.0* (IBM Corp. Released 2020. IBM SPSS Statistics for Windows, Armonk, NY: IBM Corp). Descriptive statistics were calculated for all variables.

The values were measured as median, mean, and SD according to the considered variables. Comparative analyses between WHO grade 1 and grade 2 tumors were performed using the Mann–Whitney U test for continuous variables and Fisher's exact test for categorical variables. Statistical significance set at $p<0.05$. Logistic regression analysis was used to identify independent predictors of tumor grade.

RESULTS

The study cohort comprised 15 patients diagnosed with sellar and parasellar meningiomas (tab. I), with a marked predominance of female patients (80%), compared to males (20%), resulting in a female-to-male ratio of 4: 1. The mean age at diagnosis was 60.3 ± 13.2 years, with a median of 63 years (IQR: 52–71), and an age range spanning from 32 to 76 years. There was a clear predominance of lesions arising from the sellar region [tuberculum sellae (Fig. 1) and sellar diaphragm] (66.7% of all cases), while the remaining tumors (33.3%) were located in parasellar region (Fig. 2), including the anterior clinoid process of the sphenoid bone and cavernous sinus.

The most frequently used approaches were pteryonal and fronto-temporal (46.7%), followed by frontal and bifrontal (33.3%), and endoscopic endonasal approaches (20%). Complete resection was achieved in 66.7% of patients, subtotal resection in 20% of cases, and partial resection in only 13.3% of cases.

TABLE I.

Demographic, clinical, and surgical characteristics of patients with sellar and parasellar meningiomas (n=15).

Variable	No. of cases	Percentage
Age (years)		
mean ± SD	60.3 ± 13.2	
median	63 (52-71)	
Gender		
Female	12	80%
Male	3	20%
Tumor location		
Sellar region (tuberculum sellae, sellar diaphragm)	10	66.7%
Parasellar (clinoidian, cavernous sinus)	5	33.3%
Surgical approach		
endonasal endoscopy	3	20%
pteryonal / frontotemporal	7	46,7%
frontal / bifrontal	5	33.3%
Tumor resection type		
total (macro-/microscopical)	10	66.7%
subtotal	3	20%
partial	2	13.3%
Total patients	15	100%

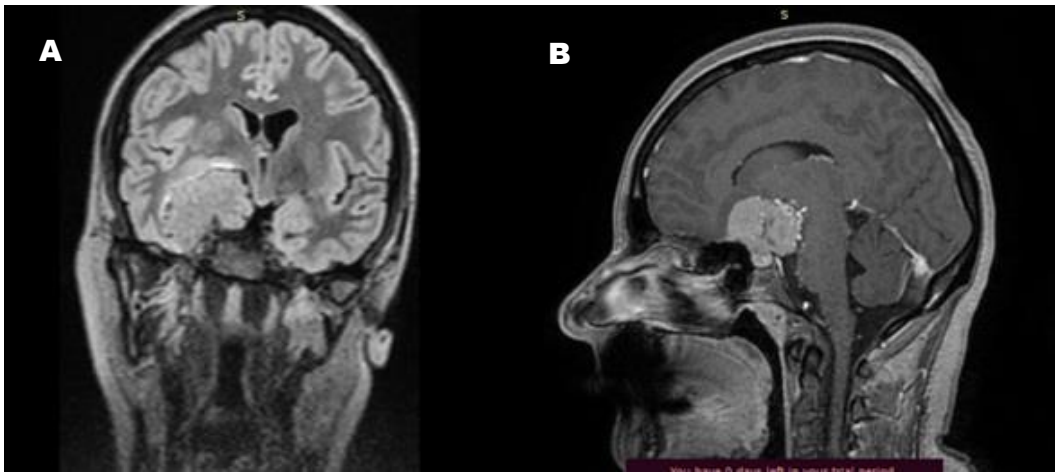

Fig. 1. Craniocerebral Magnetic Resonance Imaging (MRI) of a tuberculum sellae meningioma. (A) sagittal section.; (B) coronal section.

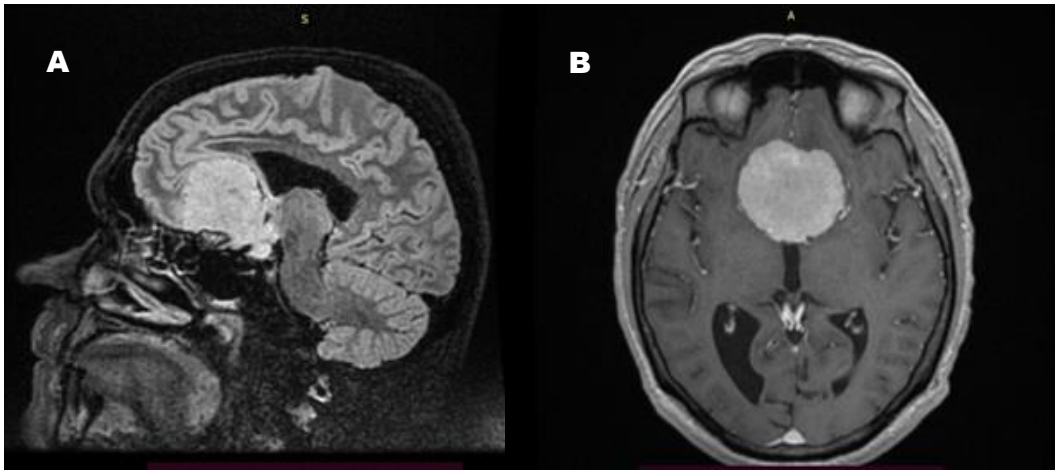

Fig. 2. Craniocerebral Magnetic Resonance Imaging (MRI) of a parasellar meningioma. (A) sagittal section.; (B) axial section.

Final histopathological analysis (tab. II) revealed a predominance of WHO grade 1 spMs (73.3%) (fig. 3), while WHO grade 2 spMs accounted for 26.7% of cases (fig. 4).

The meningothelial subtype was the most frequent (60%), followed by transitional (26.7%) (fig. 3) and secretory subtypes (6.7%). Atypical subtype represented 26.7% of all cases (fig. 4).

Dividing patients into two subgroups according to the degree of malignancy of spMs (tab. III), we found that grade 2 spM patients were younger than grade 1 spM patients (57.5 ± 18.5 years vs. 60.5 ± 12.5) but no statistical significance was found. 81.8% of cases with grade 1 spM and 75% of cases with grade 2 spM were female patients, but no statistical significance was found.

TABLE II.

Pathological characteristics of patients with sellar and parasellar meningiomas (n=15).

Variable	No. of cases	Percentage
Tumor grade (WHO, 2021)		
Grade 1	11	73.3%
Grade 2	4	26.7%
Histological subtype		
meningothelial	9	60%
transitional	4	26.7%
secretory	1	6.7%
atypical	4	26.7%

Mean percentual value of Ki-67 LI was lower (3.4 ± 1.3) in WHO grade 1 spMs (fig. 3D) and markedly increased (12.0 ± 2.2) in WHO grade 2 spMs (fig. 4D) and these data had statistical significance (p = 0.003) (tab. III, fig. 5). Mean percentual value of PR was higher (81.4 ± 14.8) in WHO grade 1 spMs (fig. 3B) and markedly decreased (42.5 ± 18.9) in WHO grade 2 spMs (fig. 4B), and these data had statistical significance (p = 0.003) (tab. III, fig. 5). Positivity of nuclear p53 was more frequently identified in WHO grade 2 sellar and parasellar meningiomas (Fig. 4C), but without statistical significance (p = 0.077) (tab. III).

TABLE III.

Comparison of demographic and surgical features, as well as immunohistochemical markers of sellar and parasellar meningiomas (n=15) according to their WHO grade.

Variable	Who Grade 1 (N = 11)	Who Grade 2 (N = 4)	p-Value
Age, years, mean ± SD	60.5 ± 12.5	57.5 ± 18.5	0.743
Age, median (IQR)	63 (56–69)	61 (52.3–66.3)	-
Female	9/11 (81.8%)	3/4 (75%)	1.000
Male	2/11 (18.2%)	1/4 (25%)	-
Ki-67, %, mean ± SD	3.4 ± 1.3	12.0 ± 2.2	0.003
Ki-67, median (IQR)	3 (3–3.5)	12.5 (11.3–13.3)	-
PR, %, mean ± SD	81.4 ± 14.8	42.5 ± 18.9	0.010
PR, median (IQR)	90 (75–90)	35 (30–47.5)	-
p53 positive	2/11 (18.2%)	3/4 (75%)	0.077
Complete resection	7/10	2/4 (50%)	0.580

We performed a logistic regression analysis for the prediction of WHO Grade 2 meningioma for the present cohort (n = 15) using tumor grade as the dependent variable (0 = Grade 1; 1 = Grade 2) and as independent variables we chose the biological variables Ki-67 LI (%), PR (%), and p53 (positive vs. negative).

Table IV shows that for every 1% increase in Ki-67 LI, the risk of diagnosing a grade 2 spM will increase by 85% and that a 1% increase in PR will decrease the risk of identifying a grade 2 spM by 8%. Regarding p53, an increased OR (≈4.5) was identified, but without statistical significance.

The model combining Ki-67, progesterone receptor expression, and p53 status demonstrated excellent discriminative ability (AUC = 1.00) for prediction of WHO grade 2 meningiomas (fig. 2), although the small sample size may lead to overestimation of performance.

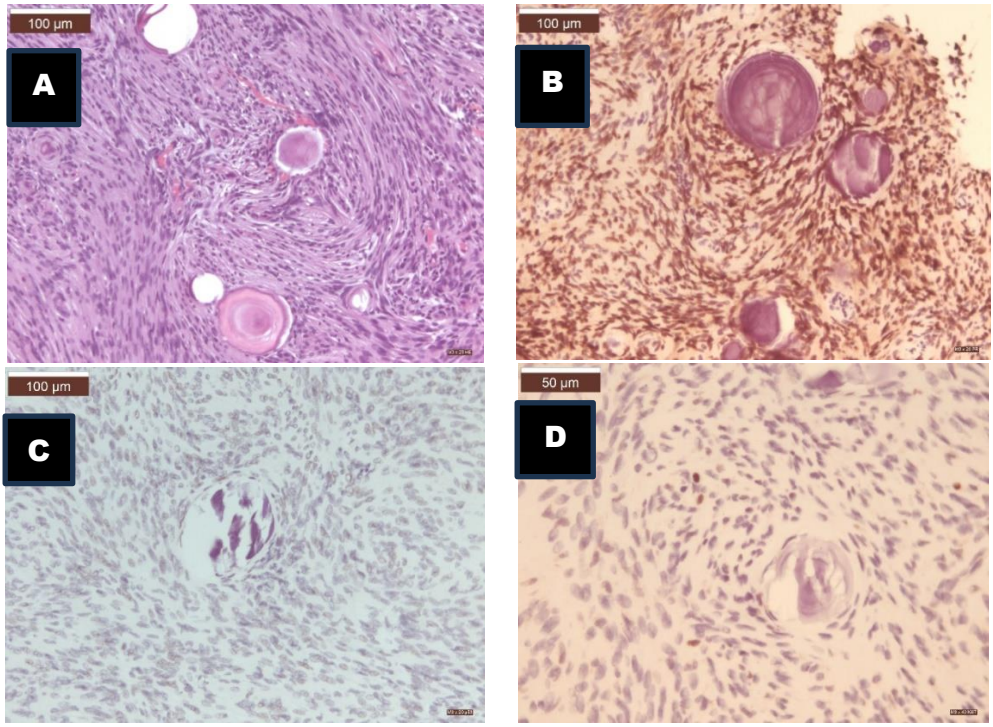

Fig. 3. Microphotographs of a grade 1 parasellar meningioma, transitional subtype. (A). Meningothelial tumor cells with fibroblastic appearance formed syncytial structures and were disposed in fascicles or whorls. The tumor cells presented indistinguishable cell membranes and bland nuclear features. Numerous psammomatous bodies were randomly scattered throughout the tumor mass. (HE, x200). (B). Almost all cells showed intense nuclear immunopositivity for Progesterone Receptor (Immunohistochemistry, x200); (C) Tumor cells did not demonstrate nuclear immunostaining for p53 (Immunohistochemistry, x200); (D). Ki67 LI exhibited low values (≤4%) (Immunohistochemistry, x400).

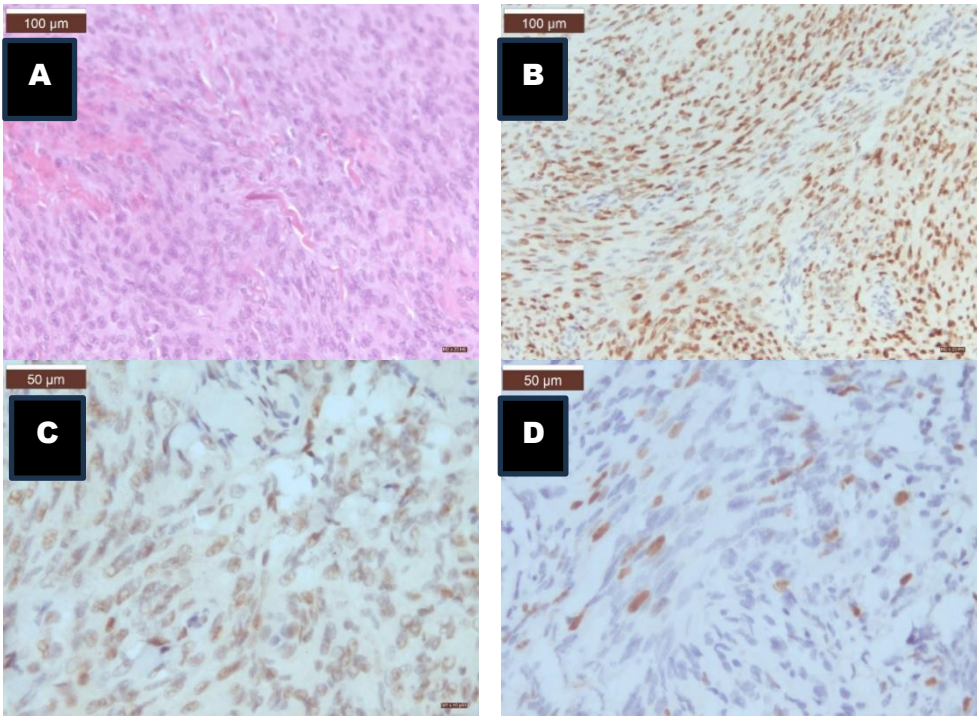

Fig. 4. WHO Grade II meningioma, atypical subtype. (A). Meningothelial tumor showing sheeting architecture, increased cellularity, and macro nucleoli (HE, x200); (B) The tumor showed nuclear immunopositivity for Progesterone Receptor varying from one area to another, with some areas having immunopositivity in 100% of the nuclei, others having it in 50% of the nuclei (Immunohistochemistry, x200); (C) Tumor cells demonstrated moderate nuclear immunostaining for p53 in almost all tumor cells (Immunohistochemistry, x400); (D). Ki67 LI exhibited higher values (Immunohistochemistry, x400).

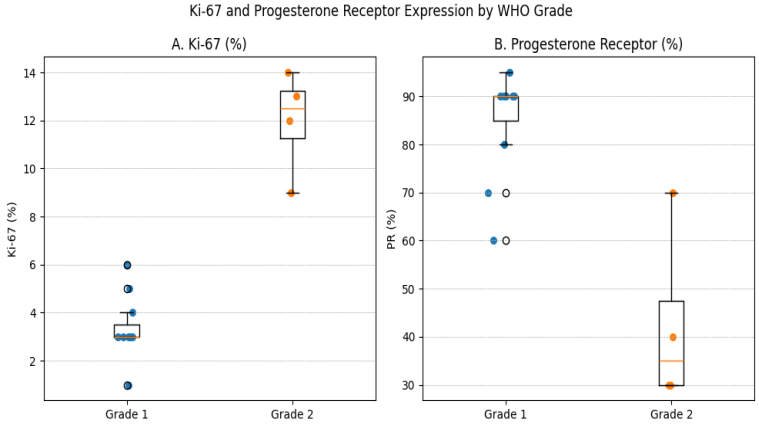

Fig. 5. Distribution of Ki-67 LI values (A) and progesterone receptor (PR) expression (B) in sellar and parasellar meningiomas according to their WHO grade.

TABLE IV.

Logistic regression analysis of immunohistochemical predictors of WHO grade 2 sellar and parasellar meningiomas in the present study

Variable	Odds Ratio (OR)	C.I. 95%	p-Value
Ki-67 (%)	1.85	1.20 – 3.90	0.01
PR (%)	0.92	0.86 – 0.98	0.02
Positive p53	4.50	0.70-35.0	0.11

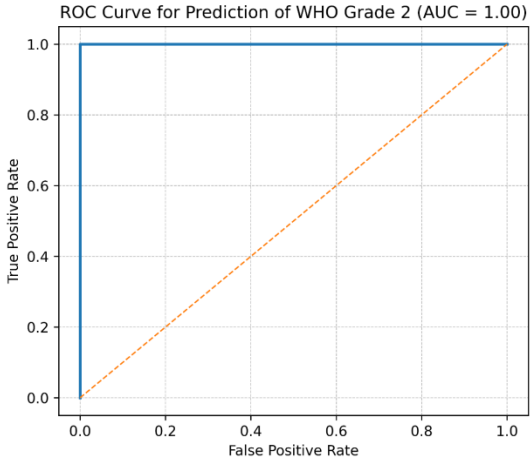

Fig. 5. Receiver operating characteristic (ROC) curve for the prediction of WHO grade 2 sella and parasellar meningiomas in the present study.

DISCUSSION

The present study provides a comprehensive clinicopathological and statistical evaluation of sellar and parasellar meningiomas. The majority of cases in our study were clustered in the sixth and seventh decades of life, which represent a decade (20) or even two decades later (21) than previous studies realized on spMs thus reflecting a particularity for the present cohort.

The majority of the patients in the present study were females, and this result was similar to the gender ratios in studies realized on meningiomas in general who found out a F: M ratio=3.8: 1 (22). But studies focusing on spMs revealed an even higher ratio. Kwancharoen *et al*. (20) highlighted the fact that spM are common in females, with F: M ratio of 6: 1.

In our study, tumor anatomical distribution highlights the predilection of spMs for development in close proximity to the optic apparatus and pituitary region, i.e. tuberculum sellae and sellar diaphragm, explaining the frequent visual and endocrinological symptoms observed in clinical practice (23, 24).

Our study also revealed a heterogeneous but anatomically tailored surgical strategy, and these data are similar to those reported by other authors (25). The fronto-temporal approach was the most used approach, and the same data was reported by some other authors in order to reduce post-surgical

morbidity (26). Our findings reflect both the technical feasibility of surgery in this region and the anatomical constraints imposed by critical neurovascular structures, particularly in parasellar tumors. SpM resection can vary, depending mostly on the tumor extension, and the pattern of growth (25, 27). In our study, a high rate of complete resection was identified and was associated with grade 1 spMs. Subtotal and partial resections were more frequently encountered in grade 2 spMs, indicating a tendency toward more complex surgical management due to infiltration of the surrounding structures.

Intracranial meningiomas, regardless of their location, are more common of the meningothelial (6) or transitional type (22, 28). Posterior fossa meningiomas are mostly of fibrous subtype (29). In the present series, which included only spMs, we identified a preponderance of the meningothelial subtype as found by other studies focused on parasellar meningiomas (17, 30).

Grade 1 spMs from the present study represented the majority of cases, followed by grade 2 spMs that represented a quarter of all analyzed cases. This proportion of higher-grade tumors is slightly elevated compared to other studies based on intracranial meningiomas in general (1, 31, 32). Thus, our results can suggest either referral bias toward complex cases or a true enrichment of biologically aggressive lesions in this anatomical region.

When comparing the subgroup of grade 1 and grade 2 spMs, we did not identify significant differences for age, sex, or extent of resection in the present cohort. Ki-67 LI showed significantly higher values in grade 2 spMs compared to grade 1 spMs, supporting the role of Ki-67 as a proliferative marker associated with histological aggressiveness. PR expression showed the opposite pattern, with higher values in grade 1 spMs and significantly reduced expression in grade 2 spMs. p53 expression was more frequent in grade 2 spMs but did not reach a statistical significance. Thus, the present study highlights the importance of integrating immunohistochemical markers into the evaluation of spMs. However, Ki-67 is a well-established marker of proliferative activity and has been consistently associated with tumor grade and recurrence (2, 33). Guresci *et al*. (34) found that the median survival of patients with meningiomas harboring Ki-67 ≤13.2% was 122 months and of those with meningioma revealing Ki67 LI > 13.2% was only 60 months ($p = 0.004$). Also, the prediction of recurrence based on Ki-67 LI had an acceptable discrimination (AUC = 0.74).

For the present cohort, Ki-67 Li was also shown to be an independent predictor for spMs. Ki-67 LI is not just a descriptive marker, but a major biological determinant of tumor aggressiveness. On the other hand, the results of the present study also showed that PR has an independent protective role for spMs, an aspect also confirmed by Aung *et al*. (35), who showed that high values of PR in meningiomas were associated with longer recurrence-free survival.

We found an inverse correlation between PR expression and malignancy grade of spMs and this fact is also clinically relevant being of interest in predicting tumor aggressiveness and guiding postoperative management. Loss of PR expression may indicate dedifferentiation and increased proliferative potential, i.e. tumor aggressiveness. Similar findings were reported in large cohorts and meta-analyses (35-38).

In the present study, although p53 was

more frequently positive in grade 2 spMs, it did not reach statistical significance in the adjusted model. Therefore, in our cohort, p53 acted as an auxiliary marker, not as a primary determinant. Also, in the literature, p53 is considered a marker of genomic instability, an aspect previously observed by some of the authors of the present study in other types of brain tumors (39), and not an independent predictor for tumor aggressiveness (2, 33). Its role is more evident in grade 3 meningiomas or recurrent tumors (40, 41).

In the present research, using logistic regression analysis, we identified Ki-67 LI and PR expression as independent predictors of WHO grade 2 spMs. The same results were obtained by Akca and Gökçe for intracranial meningiomas (37).

Our predictive model provides a practical clinical tool for estimating the probability of higher-grade spMs based on routinely available parameters.

Combining histology, immunohistochemistry, and statistical methods, these findings align with the broader trend in neuro-oncology (42) toward integrative predictive models to improve clinical decision-making.

CONCLUSIONS

The present cohort of sellar and parasellar meningiomas demonstrated a typical epidemiological and anatomical profile, combined with a relatively high proportion of grade 2 tumors, and a biologically meaningful immunohistochemical pattern. The present study demonstrates that the behavior of sellar and parasellar meningiomas is primarily driven by tumor biology rather than age, gender or anatomical location. Ki-67 Labeling Index and Progesterone Receptor expression are complementary and independent predictors of tumor grade in sellar and parasellar meningiomas. Their combined assessment provides valuable insights into tumor biology and may improve clinical decision-making. The integration of these two immunohistochemical markers into routine evaluation supports a more personalized approach to meningioma management.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

MULTIDISCIPLINARY MANAGEMENT OF COMPLEX BALLISTIC CERVICAL TRAUMA. CASE REPORT (Abstract): Accidental explosion of a projectile in peacetime is very rare. Ballistic trauma can be fatal or cause long-term consequences. Cervical trauma is associated with comminuted bone fracture, dilacerations of muscle fibers, vascular and nerve compression with or without complex lesions of the upper aerodigestive and respiratory tract. It is a rare situation that a projectile fragment passes through the face and neck without damaging vital structures. Considering the multiple lesional aspects, especially at the level of the cervical area where there are many vital visceral structures, a concise clinical, laboratory and multidisciplinary assessment is required to ensure the therapeutic success. We present such a case from our experience managed with a multidisciplinary team approach.
Keywords: BALLISTIC TRAUMA, FOREIGN BODY, MULTIDISCIPLINARY APPROACH.

Complex lesions of the head and neck of ballistic etiology are rarely described in the literature, generally in case reports from armed conflict zones. However, there are fewer reports of accidentally exploding shells dating from the World War II in areas outside the war zones (1). Most of the deaths occurring after ballistic cervical trauma are caused by vascular injuries in the aerodigestive and respiratory tracts, vertebral column or calvarium (2). The questions surrounding the optimal management of cervical trauma are related to exploratory surgery in emergency or to selective surgical approach after some investigations to decrease the rates of morbidity and mortality. In this paper we present the approach and the management of a patient who was admitted in the emergency department with complex craniofacial and cervical ballistic trauma.

CASE REPORT

In the present study we report the case of a 52-year-old, male patient which was brought into the Emergency Room of the

"Sf. Spiridon" County Clinical Emergency Hospital in March 2015, with complex injuries caused by an accidental explosion of a 76 millimeters projectile from World War II. At the first examination, the patient was in a serious condition, being intubated and mechanically ventilated. The clinical examination revealed right periorbital hematoma, asymmetric face, discontinuous bone contours, abnormal bone mobility of the right part of the face, right-side chin concussion wound in the 1/3 superior part, tenderness of the cutaneous and subcutaneous plans in upper posterior third of the neck, without any identified exit wound of the projectile fragment.

Initially we performed a neck X-ray (fig. 1) and a computed tomography which revealed comminuted fracture with displacement of the lateral and anterior wall of the right maxillary sinus (fig. 2), right zygomatic arch, lateral wall of right orbit, external process of the right pterygoid apophysis, and mandibular fracture of the right ascending ranch. It was also observed a metallic foreign body with a maximum diameter of 34 mm, positioned on the soft tissues from the right posterior cervical region at C1, C2, C3 level (fig. 3). The CT showed a fracture of the transverse process of the atlas and possible fracture of the right carotid channel with gas bubbles, fluid collection with maximum dimensions of 10.2/30.2 mm and a 55 mm craniocaudal extension of the head on the right side, located between posterior cervical muscles, semi spinal, and splenius. One of the right posterior veins, accompanying the splenius muscle was dilated in its lower part, and its upper part was apparently intercepted by the metallic foreign body.

Fig. 1. X-ray-Foreign bogy located in the right posterior cervical region.

Fig. 2. CT-comminuted fracture with displacement of the lateral and anterior wall of the right maxillary sinus

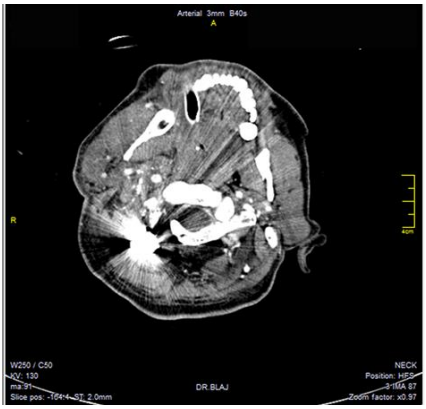

Fig. 3. CT-metallic foreign body located in the right posterior cervical region.

The patient was evaluated by a multidisciplinary surgeons' team: ENT, maxillofacial, ophthalmologist and neurosurgeon. The primary surgical approach consisted in an eschilectomy, reduction and immobilization of the orbital wall through the maxillary sinus approach and osteosynthesis of right ascending part of the mandible by the oromaxilofacial surgeon. Postoperatively, the patient showed confusional state, dysphonia and marked dysphagia. ENT evaluation and fibroscopy examination detected an adductor paralysis of the right vocal cord, salivary stasis in the right piriform sinus without swelling and hematoma of the oro- and hypopharynx. The upper gastrointestinal endoscopy performed during the gastroenterological exam excluded an intrinsic or extrinsic obstructive cause at this level. Computed tomographic reassessment highlighted-besides the presence of the foreign body and cervical collection-the presence of an 42 mm wide edema in the upper portion of right para pharyngeal space with bulging of pharyngeal wall and obliteration of the fat layer at the level of right carotid space, without perivascular extravasated during injection, right jugular vein compression in the upper portion from the exit of the skull base, deficiency filling for a distance of 45 mm, including the jugular foramen.

The second surgical phase involved an intervention performed by a mixed surgical team of ENT and neurosurgeon. The collection was located intraoperatively in the right paravertebral space C1-C4 and after aspiration of secretions was identified the foreign body with a prismatic shape of 3.0/2.0/2.5 cm, metallic nature, ash-gray color. The foreign body was extracted, and the remnant cavity was explored internally – in intimate contact with the lateral portion of C1-C4, externally-the muscle plane, anterior-prior to about 8 cm continuing with paths that dissected away the right retrostilian part of para pharyngeal space. All plans showed necrotizing fasciitis and identified a bone splinter with sharp edges about 2.0/1.5 cm, which was extracted. The surgical team performed a surgical toilet of the plans, washing with diluted Betadine solution, hemostasis, debris removal; they placed a drain in the wound cavity and realized a partial suture. Subsequently, the patient received antibiotic, analgesic, steroid anti-inflammatory, and anticoagulant therapy, anti-tetanus vaccination, nutritional supplement and topical wound bandage. The evolution was favorable permitting drain suppression, secondary suture of the wound and hospital discharge after 30 days. The 3-month follow–up of the patient showed improvement of right vocal cords mobility.

DISCUSSION

The neck is divided into three zones, by imaginary horizontal lines traced through the collarbone, cricoid cartilage, mandible angle and base of skull. These are used in the evaluation and treatment of penetrating neck injuries (3, 4). The classification system of penetrating facial trauma involves two entry areas: the face and mandible (4, 5, 6). To understand the complexity of the injuries caused by exploded projectiles, some notions of ballistic physics are necessary: external lesion, the path and terminal lesion. Once the projectile fragment penetrates the skin it will destroy and crush the tissues, the complexity of the wound being directly proportional to the input speed and with the shock wave that radiates outwards resulting in stretching, shearing and then collapse them. A small gateway can hide

massive internal injuries that are not visible at first medical evaluation (1). Cervical region involves a vital risk because of the anatomical noble elements, both visceral and neurovascular, which lack the protection of a skeleton bone (7, 8, 9).

The appearance of gunshot entrance wounds on the body depends upon many factors including, the type of firearm, the type of ammunition, the location of the wound on the body, and the circumstances of how a wound was sustained (10). The capacity of the penetrating projectile to destroy and dislocate tissue is defined by its kinetic energy, but the real tissue injury is related to the manner of energy release during the contact between the projectile and the tissue and to the physical characteristics of tissues and organs involved (resistance to tension, physical sizes of an organ, and the existence or absence of surrounding anatomical limitations (2,11). Therefore, the ratio of energy transmission to the tissues along the wound trajectory is influenced by some projectile features, as profile, structure, and stability. At the level of tissue injury can be recognized two areas: a cavity created by the passage of the projectile and the contused tissue surrounding it, created principally by transitory cavitation which is an indicator of real high-energy assignment to tissue. Consequently, the wound assessment and the type of necessary treatment must be centered on the understanding of the mechanisms contributing to tissue impairment (12, 13). The surgeon can promptly evaluate the tissue injury in a patient if he knows the type of missiles and features related to wound profile as the penetration complexity, the ammunition distortion/fragmentation, diameter of the permanent and temporary wound cavity (13).

Primary evaluation, in emergency, involves stabilization of breathing and circulatory functions, as well as injuries that may be life threatening. In most cases, medical history, physical examination, laboratory investigation, and treatment are done simultaneously. They are performed by a multidisciplinary team consisting of surgeons (ENT, maxillofacial, neurosurgery, vascular, plastic) and intensive care specialists, who will determine lesion characteristics and treatment priorities. The ideal time and treatment choice remain a continuous discussion within this subject (14, 15). In our case, the surgical extraction of the projectile fragment was not a priority because it has not started to migrate, and it was not a danger for the vital structures of the neck. Subsequently, priority was given to the maxillary and mandibular fixation. Although, the belief that projectiles are sterilized by the heat is false, and the antibiotic administration is questionable (16), in this case we administered intravenous doses of vancomycin, meropenem and ceftriaxone.

CONCLUSIONS

Our study confirms that ballistic cervical trauma is associated with high risks, requiring emergency treatment and a multidisciplinary approach for collaboratively developing a treatment plan. Particularities of this case consist in defining the mechanism of cervical trauma, accidental explosion of a projectile outside armed conflict areas and surgical therapeutic approach with a mixed team to ensure a high survival rate, optimal healing with prevention of postoperative complications and sequels.

ROLE OF COMPUTED TOMOGRAPHY IN THE EVALUATION OF THE PATIENT WITH HEPATITIS C-RELATED LIVER CIRRHOSIS (Abstract): Cirrhosis is an increasing cause of morbidity and mortality, one of the most common causes being hepatitis C virus (HCV) infection. Diagnosis, staging and complication assessment are equally important in patients' management, as well as establishing the right indication for antiviral treatment and further follow-up. So far, it is well recognized the role of multidetector computed tomography (MDCT) in the evaluation of focal liver lesions in the cirrhotic liver, while its capabilities of describing morphological changes of the liver and the extrahepatic response to increased portal pressure is less extensively used. The aim of this review is to underline the utility of MDCT as a useful complementary tool in the evaluation of patients with hepatitis C-related cirrhosis. **Keywords:** CIRRHOSIS, HEPATITIS C VIRUS, COMPUTED TOMOGRAPHY, HEPATOCELLULAR CARCINOMA, MORPHOLOGICAL CHANGES OF LIVER.

Cirrhosis is the final stage of chronic liver diseases. Even if there are many possible causes of chronic liver injury, the histological pathway is similar, characterized by fibrosis and change of normal liver structure into a distorted architecture consisting in regeneration nodules. Moreover, there is vascular remodeling, which results in the formation of intrahepatic shunts of the arterial and portal vessels into the central vein and impairment of the exchange between liver parenchyma and sinusoids (1).

In the more developed countries, the main causes of cirrhosis are: hepatitis C virus (HCV) infection - the leading cause of liver-related morbidity and mortality worldwide (2), alcoholic liver disease, non-alcoholic fatty liver diseases, hepatitis B virus, and others (the most common being autoimmune hepatitis, hereditary liver diseases, drug-induced liver disease) (3, 4). A recent study covering the geographic area of Europe has estimated that the prevalence of HCV ranges from 2.4% in Western and Central Europe to 2.9% for Eastern Europe (5). The risk and progression of fibrosis associated with HCV have been correlated with host factor rather than viral factor: there is no relationship between viral load and genotype and the severity of fibrosis, the human promoter polymorphism appears to correlate with fibrosis and host immune phenotype may be critical, with more rapid progression in

immunosuppressed patients (6).

In the present days, interferon (IFN)-free treatment represents the paradigm for treatment of chronic hepatitis C with high rates of sustained virologic response (SVR). Several recent and ongoing studies show that IFN-free regimens using direct-acting antiviral (DAA) combinations can cure most chronically infected HCV patients (7).

The progression of liver fibrosis is not a continuous process but rather has a non-linear course depending of various factors like sex, age, alcohol consumption and obesity. The former gold standard liver biopsy is currently considered insufficient for frequent monitoring because of its disadvantages: it is expensive, may have complications and its accuracy suffers from sampling variation. The ideal noninvasive liver fibrosis assessment should be simple, accurate, inexpensive and widely available (8). The new noninvasive methods in use today have two different but complementary approaches: the biological approach based on the quantification of biomarkers in serum samples and the physical approach based on the stiffness of liver parenchyma, a more specific marker (9). Liver stiffness is measured by using transient elastography, acoustic radiation force impulse imaging (ARFI) and magnetic resonance (MR) elastography. These noninvasive methods are widely used and have equal advantages and limitations. Serum tests are not specific to the liver, unable to discriminate between intermediate stages of cirrhosis, and the results are not immediately available. Transient elastography requires a dedicated device and region of interest cannot be chosen, has low applicability in obesity and ascites. MR elastography is time-consuming and costly, and is not applicable in iron load (9, 10).

CT has been considered insufficient as a non-invasive method of staging fibrosis in comparison with ultrasound elastography and laboratory testing, or magnetic resonance (11). Along with the advantages of being a widely used, reliable and affordable examination, nowadays there is some progress in new approach techniques that may promise the utility of CT in the detection and precise staging of fibrosis.

The main use of CT examination is the detection of hepatocellular carcinoma (HCC), the most fearsome complication, especially in patients with high serum α-fetoprotein levels, which are at the highest risk. Also, there are some concerns related to the higher incidence of HCC following IFN-free antiviral therapy, most likely a consequence of the removal of the upregulated inflammatory status as a control mechanism of the new malignant cell growth (12).

The aim of this article is to illustrate the main aspects of the pathological process as they appear on CT examination, underline the morphological transformation of the liver in volume and shape, the structural and textural changes.

Liver assessment

Morphological changes in the liver vary with the stage of fibrosis. Hepatomegaly is the early sign in more than 60% of patients (13). As the disease progresses there is an architectural change and, due to the alteration in portal blood flow, one theory suggests that the blood does not mix well and "streams" do occur (14). The right lobe receives most of its blood from the superior mesenteric vein so it is more exposed to toxins and the consequence is the atrophy

of the right lobe posterior segments (VI and VII) and medial segment of the left lobe (IV). On the other side, the left lobe receives blood from the splenic vein and is more exposed to the pancreatic hormones that promote hypertrophy, so there will be an enlargement of the lateral segments of the left lobe (II and III). Caudate lobe enlargement is due to the supply of left branches or bifurcation of portal vein, and because the flow is increased by the shorter intrahepatic course of the branches (15).

The typical appearance of the cirrhotic liver on CT is transversal enlargement of lateral segments and atrophy of the medial segment of the left lobe and atrophy of the posterior segments of right lobe and hypertrophy of the caudate lobe (fig. 1).

An important consequence of this liver remodeling is the presence of right hepatic notch sign defined as a sharp indentation developed between the caudate and right lobe of the liver (fig. 2). The presence of hepatic notch is a qualitative method for assessing the hypertrophy of the caudate lobe and atrophy of the right lobe (16).

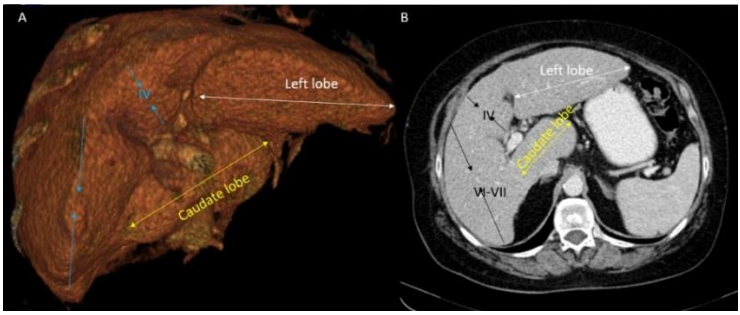

Fig. 1. Volume rendering image (A) and axial section (B). Typical appearance of the cirrhotic liver: enlargement of the lateral segment of the left lobe and atrophy of the medial segment with classical "tongue-like" appearance of the left lobe, enlargement of the caudate lobe and shrinking of the posterior segments of the right lobe.

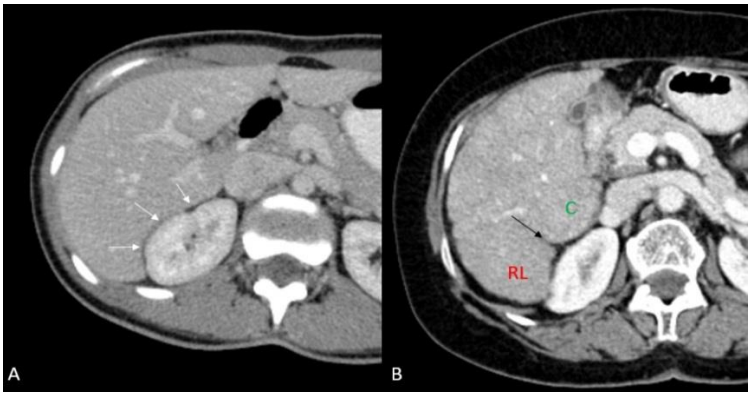

Fig. 2. (A) The posterior - inferior surface of the right hepatic lobe at the level of the right kidney is normally concave owing to the renal impression (white arrows) (B) In patients with cirrhosis a sharp indentation develops between the caudate and the right lobe of the liver.

Other morphological changes seen in cirrhosis are: blunt liver margins, widening of the periportal space, expansion of the pericolecystic space and enlargement of the interlobar fissure (17).

Widening of the periportal space is a consequence of segment IV atrophy. Although the exact mechanism remains unclear, it is believed to be related to portal vein hypoperfusion. An enlarged hilar periportal space, defined as a distance between the right portal vein and the posterior edge of segment IV greater than 10 mm, may be the only morphological sign in earlier stages of cirrhosis.

In normal liver, the gallbladder fossa is delimited laterally by the right lobe and medially by segment IV, and contains little fat. In cirrhotic liver, the gallbladder fossa can be enlarged. The expanded gallbladder fossa in cirrhosis may be the consequence of four factors: atrophy of the medial segment of the left hepatic lobe and hypertrophy of the caudate lobe, atrophy of the anterior segment of the right hepatic lobe with counterclockwise rotation of the major interlobar fissure and enlargement in the cephalocaudal direction of the left hepatic lobe (13, 18).

Hypertrophy of the caudate lobe and atrophy of the right lobe were at the basis of the attempts to stage fibrosis. There are few studies investigating the accuracy of CT findings in liver fibrosis: In 1980 Harbin *et al.* (19) developed a cirrhosis score using the ratio of the width of the transverse caudate lobe to the width of the transverse right lobe, a ratio > 0.65 is 96% and > 0.73 is 99% likely to be cirrhotic (fig. 3). Because the hypertrophied caudate lobe extended beyond the main portal vein bifurcation, in 2002 Awaya *et al.* (15) used a modified version of this ratio with much more sensitivity using the bifurcation of the right portal vein as a landmark.

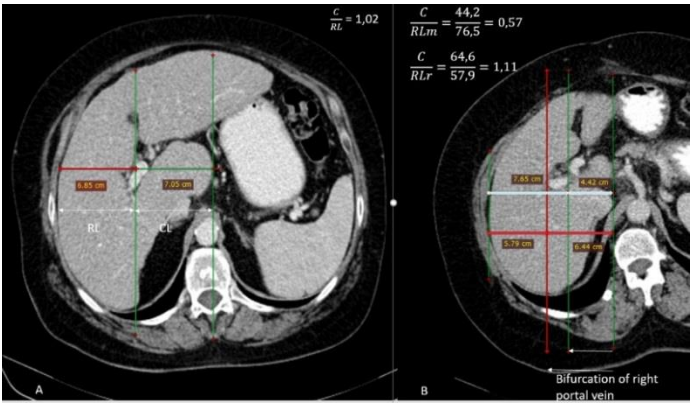

Fig. 3. (A) Harbin method image: axial slice immediately below the bifurcation of the main portal vein line 1: parasagittal line drawn through the right lateral border of the portal vein, line 2: parasagittal line drawn through the left lateral border of the caudate lobe, line 3: line orthogonal to lines 1 and 2 midways between the portal vein and the IVC extended to the right liver edge. RL measurement: along line 3, from right liver edge to line 1. C measurement: along line 3, between line 1 and line 2. Caudate-right lobe ratio: C/RL. (B) Hypertrophied caudate lobe extended beyond the main portal vein bifurcation and modified C/RL uses the bifurcation of the right portal vein as a landmark. A ratio greater than 0.55 suggested a diagnosis of cirrhosis.

The latest attempt was in 2014, when Huber *et al.* (20) used the sum diameters of the hepatic vein divided by modified caudate - right lobe ratio with a sensitivity of 83% and a specificity of 76% for precirrhotic liver fibrosis, and a sensitivity of 88% and a specificity of 82% for cirrhotic liver fibrosis (fig. 4).

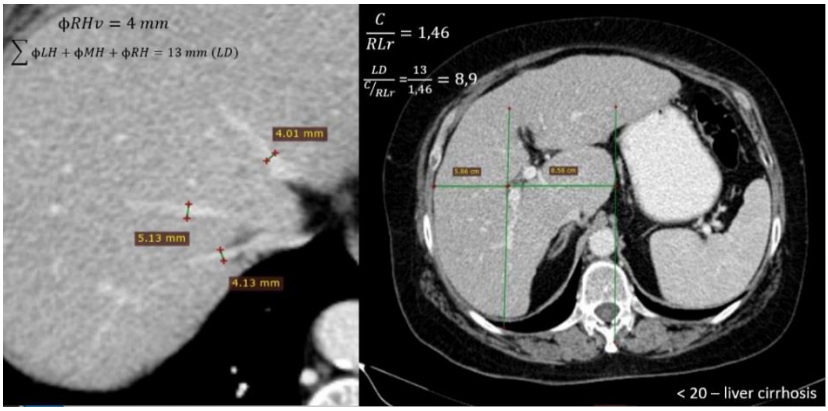

Fig. 4. Patient with right hepatic vein smaller than 9 mm, the ratio of the sum of hepatic vein divided by the modified caudate-right hepatic lobe diameter is 8.9, and is suggestive for cirrhosis.

Contour and texture changes

Diffuse fibrosis is the main cause of heterogeneity of the liver. It is better seen on unenhanced CT and may have four different patterns of distribution: poorly defined region of low attenuation, thin perilobular bands of low attenuation, thick bridging bands of low attenuation, and diffuse fibrosis causing perilobular cuffing (21) (fig. 5).

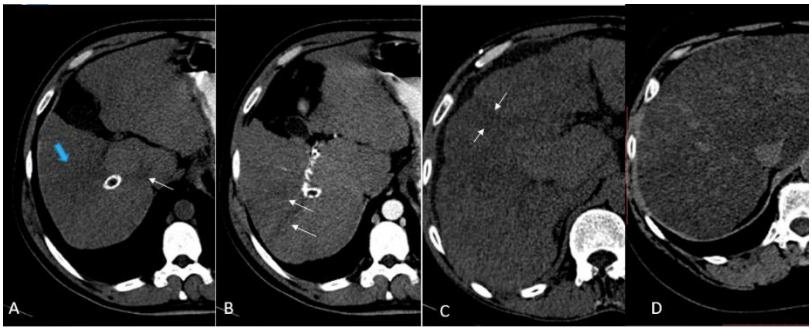

Fig. 5. Different patterns of diffuse fibrosis are seen on CT: (A) Patchy, poorly defined region of low attenuation, (B) Thin perilobular bands of low attenuation, (C) Thick bridging bands of low attenuation (D) Diffuse fibrosis with perilobular cuffing.

Surface nodularity is a direct consequence of the presence of regenerative nodule. The liver contour may be smooth, nodular, fine to coarse if they are < 3 cm,

or grossly lobular if they are more the 3-cm diameter (22) (fig. 6). This direct relationship between hepatic distortion and the surface embossing may predict the underlying hepatic fibrosis.

Recent studies tried to use liver surface nodularity as a biomarker to allow CT examination alone to accurately discriminate between stages of liver fibrosis comparable to elastography (23, 24). Moreover, a multiparametric analysis is possible in a near future, using a combination between the liver surface nodularity quantification and other CT biomarkers that are already available, like the volumetric and textural features (24).

The diagnosis of liver cirrhosis based on selected independent variables, such as irregular and nodular surface, parenchymal abnormalities, morphological changes, and manifestation of portal hypertension has in one study by Kudo et al (25) an accuracy of 71.9%, sensitivity of 77.1% and specificity of 67.5%.

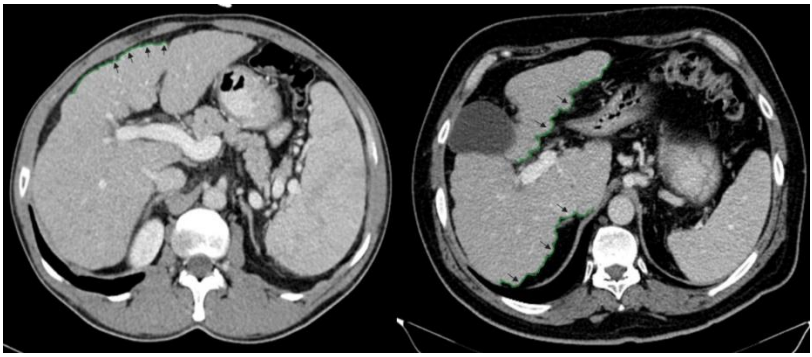

Fig. 6. Fine nodularity of liver contour, (left image) "cobblestone" margin (right image).

Regenerative nodules, dysplastic nodules, and hepatocellular carcinoma

Regenerative nodules (RNs) are defined as an area of liver parenchyma enlarged in response to necrosis and altered circulation or other stimuli, and are surrounded by fibrous septae. According to size, RNs are micronodules if they have less than 3 mm, or macro nodules if they are equal or more than 3 mm. If greater than 15 mm they may harbor dysplastic or malignant foci (26). RNs are present in all cirrhotic livers, but they are revealed in only 25% of unenhanced CT scans. Nodules are difficult to detect on CT because they are too small and like the surrounding tissue (fig. 7). They are detectable when surrounded by hypodense fibrotic bands or when they accumulate iron (siderotic nodules) (21).

A dysplastic nodule (DN) is defined as a nodular region of dysplastic hepatocytes of at least 1 mm in diameter without histologic features of malignancy. DNs are considered an intermediate stage in the progression to hepatocellular carcinoma. They are classified according to histological atypia into low-grade dysplastic nodules, which are composed of hepatocytes that are minimally abnormal, and high-grade dysplastic nodules which have any of the features of low-grade nodules but in addition have one or more of the following: high nuclear-cytoplasmic ratio, irregular nuclear contour, nuclear hyperchromatic, rare mitotic figures, pseudo-gland formation, cytoplasmic basophilia, and resistance to iron accumulation (27).

The prevalence of DNs in patients with cirrhosis ranges from 14% to 37%, but they are not easily distinguishable from the regenerative nodules in the surrounding liver (28). Most of DNs are undetectable by CT. Occasionally there may be a slightly hyperattenuating nodule on non-enhanced scan but without postcontrast enhancement. Tumor angiogenesis seems to be a required step in the progression from regenerative nodule to dysplastic nodule (low-grade to high-grade) and, finally to HCC. During this process, there is a conversion of the vascular supply with an increase in the arterial and decrease in the portal supply. The less differentiated nodules enhance more on postcontrast in early arterial phase and may mimic HCC on CT scan.

HCV promotes carcinogenesis having a direct and indirect role, especially due to fibrosis. In this situation, the chromosomal alteration that occurs in fibrotic tissue is associated with tumor genesis. Another way to promote carcinogenesis is through chronic inflammation of the liver which has been associated with a shift in signaling from tumor suppression to fibrosis and carcinogenesis (29).

HCC is a malignant neoplasm composed of cells with hepatocellular differentiation and is histologically classified as trabecular, pseudo glandular, compact and scirrhous. The most common is the trabecular type.

The classical CT features of the HCC are a solitary nodule on non-enhanced scan, often inhomogeneous due to necrosis. Almost all HCCs are highly vascular lesions and exhibit intense contrast enhancement during the arterial phase. Due to the alteration in vascular supply with an increased arterial and decreased portal blood supply, they exhibit washout in the portal phase. Another important CT finding is the presence of the fibrous capsule which is usually enhanced on delayed equilibrium phase images.

Another less common appearance is as an infiltrating mass, a multicentric lesion (mass with daughter lesions) or multifocal lesion (may mimic metastasis).

Liver Imaging Reporting and Data System (LI-RADS) was created by the American College of Radiology and is both a set of standardized terminologies and a classification system for imaging findings in liver lesions. The classification system is meant to be used in livers which have risks factor for HCC. The most suitable are the patients with liver cirrhosis, especially those with HCV infection who are at the greatest risk.

The latest version in use is ver. 2014 applicable to CT and MR and for contrast enhanced ultrasound (CEUS LI-RADS). The advantages of the method are the decrease in error of interpretation by applying the consistent terminology and enabling the communication with the clinician and increased therapeutic performance.

The "observation" is the preferred term for the CT findings which is described using major criteria and ancillary features. Major criteria are: hepatic phase enhancement, washout, capsule, or pseudo capsule and threshold growth. For each of these we have a binary categorization: present or not present. In the dubitative situation, the ancillary features mainly on MR evaluation which may favor malignancy or benignity are used. If assignment is unclear, ancillary findings may be used as "tie-breaker". The LI-RADS scores range from L-1 which favor benignity to L-5 which favor malignancy (30, 31).

The first two categories are LR-1 benign

and LR-2 probably benign. Such lesions as cysts, hemangioma, vascular anomaly, perfusion alteration, hypertrophic pseudo mass, confluent hepatic fibrosis, focal scar, and lesions which disappear at follow-up without treatment are LR-1. Lesions which have an atypical appearance of the benign entities and cirrhosis-associated nodules are categorized as LR -2.

Observations that are neither definitely or probably benign are categorized based on their diameter and the following features: washout, capsule, or threshold growth in one of the category.

The intermediate probability for HCC is assigned as LR-3 observation, which has a moderate probability of both benign entity and HCC (fig. 8).

LR-4 category is assigned when the imaging features are suggestive, but not diagnostic, of HCC (fig. 9).

LR-5 category is assigned only when there is 100% certainty that the observation is HCC or is proven to be HCC at histology. LR-5V category is assigned when there is definite enhancing soft tissue in a vein irrespective of the presence or absence of visible intraparenchymal HCC. Finally, LR-M is a special category assigned to observations that are probably malignant but not specific for HCC, like metastasis, lymphoma, cholangiocarcinoma (fig. 10).

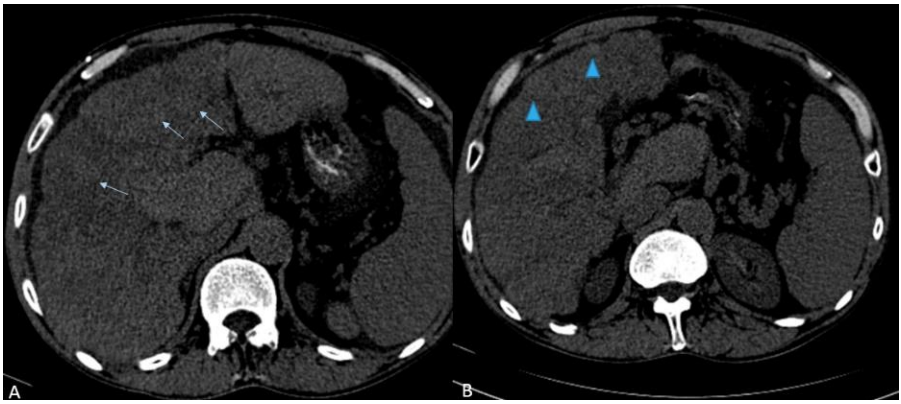

Fig. 7. (A) Regenerative nodules (arrow) surrounded by lower attenuation fibrosis, (B) High-attenuation nodule (arrowhead).

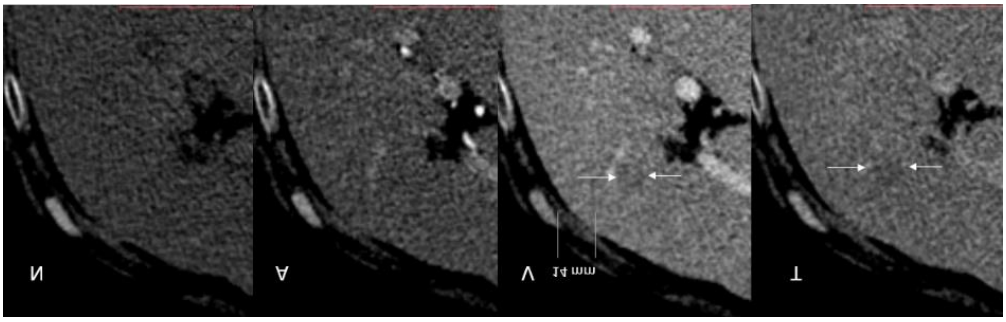

Fig. 8. LR-3 observation. Liver nodule (< 20 mm) isoattenuation to the surrounding liver in arterial phase, and hypoattenuating in the portal and equilibrium phase (washout).

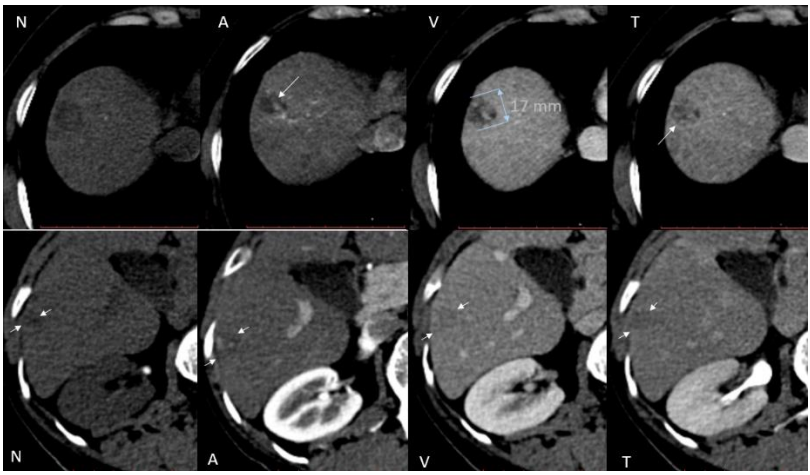

Fig. 9. LR-4 observation. First row: 17-mm nodule with partial hyperenhancement in arterial phase and capsule in delayed phase;
Second row: nodule with partial hyperenhancement in arterial phase and hypo enhancement in venous and delayed phase (washout) but without capsule in delayed phase.

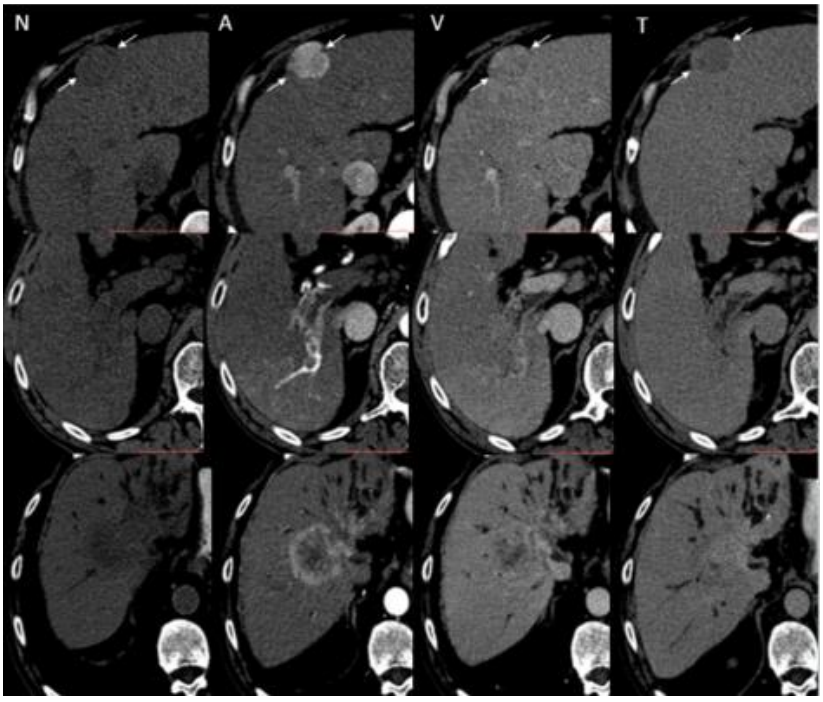

Fig. 10. LR-5 observation (first row) - a large subcapsular mass with arterial hyperenhancement, washout and capsule in delayed phase. LR-5V (second row) - enhanced tumor tissue into right portal vein. LR-M (bottom row) - mass with dynamic enhancement suggestive for cholangiocarcinoma. Note the dilated bile ducts in the left liver lobe.

Repercussion on the extrahepatic abdominal organs in cirrhosis

Extrahepatic abnormalities associated with cirrhosis are mainly a consequence of portal hypertension defined as a pressure greater than 5-10 mm Hg. As the pressure in the portal system increases due to the distortion of the hepatic vasculature and fibrosis, the blood flow is shunted away from the liver to the low pressure systemic vessels and the portosystemic collaterals develop.

The main abdominal manifestations are dilated portal vein, varices, splenomegaly, ascites and bowel wall and mesenteric edema.

Varices appear as a serpentine or tubular structure that enhance after contrast administration. They are located most frequently in the wall of the esophagus and appear as s nodular intraluminal protrusion. Gastroesophageal bleeding is the most common clinical presentation. Another frequent location is in lesser omentum from the left gastric collaterals present in 80% of the patients. Varices can occur on the collateral paraumbilical vessel which communicates with the vessel located in the subcutaneous abdominal wall and reassembling a radial distribution called *caput medusae*. Portosystemic shunts commonly involve the gastrorenal and splenorenal systems (fig. 11). Nonmalignant portal vein thrombosis may occur in cirrhotic patients and is correlated with the severity of liver disease (32).

Splenomegaly is a result of portal congestion, tissue hyperplasia, and fibrosis. There is a vicious circle: the enlarged spleen requires an increased blood flow which perpetuates the underlying portal hypertension (33).

The exact pathophysiologic mechanism leading to edema of the gallbladder wall is due to a combination of factors: elevated portal venous pressure, elevated systemic venous pressure, and decreased intravascular osmotic pressure. In cirrhotic patients, the gallbladder wall is often thickened measuring more than 5 mm and hypodense (fig. 11).

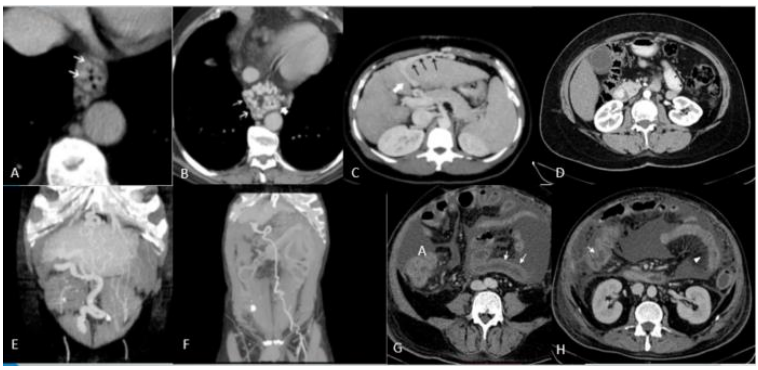

Fig. 11. CT appearances of esophageal varices. Intraluminal protrusion with scalloped margins (arrows) (A). Paraoesophageal varices (white double arrows) appear as well defined, round, tubular, or serpentine structures situated outside the wall of the esophagus in the mediastinum (B). Dilated paraumbilical veins (C) anterior to the left hepatic lobe (black arrows) arising from the left portal vein (white arrow). Abdominal wall varices radiating from the umbilicus. Connection with inferior epigastric veins (F) and multiple vessels forming *caput medusae* (E). Thickened gallbladder wall (D). Small bowel wall thickening in a patient with hepatic cirrhosis. CT images show diffuse thickening of the small bowel and colon wall and folds (arrows). Ascites (G) and mesenteric edema (arrowheads) are noted (H).

Ascites develops when the portal venous pressure exceeds 12 mmHg and is due to increased intravascular hydrostatic pressure and decrease in oncotic pressure. Ascites is visible as a large fluid accumulation into the peritoneal cavity with central displacement of the small bowel and mesentery.

Gastrointestinal wall thickening is mainly caused by edema and has a multisegmental distribution. The jejunum and ascending colon are most often involved and the haustral thickening of the colon is more common than wall thickening. The involvement of other digestive segments such as the duodenum, jejunum, or transverse colon without involvement of the jejunum or ascending colon may have a non-cirrhotic cause like inflammatory, ischemic, and neoplastic disease. Such CT findings should determine the search for another coexisting cause of thickening (34).

Diffuse intra- and retroperitoneal edema may have multiple causes but the most obvious mechanism is portal hypertension which causes increased hydrostatic pressure in the mesenteric vessel and extravasation of the fluid into the mesentery. Often, mesenteric edema is mild and focal and it becomes more diffuse as its severity increases. Presence of omental and retroperitoneal edema are signs of severity and correlates with other findings like severe ascites, subcutaneous edema or pleural effusion (35).

CONCLUSIONS

In our opinion, there is a need for an imaging tool able to monitor the cirrhotic patient, especially after antiviral treatment, and CT might be this tool. CT has been considered inferior to other methods (such as Fibroscan®, serum test and MR) for the noninvasive diagnosis of liver fibrosis, but is fast, widely accessible, and affordable and now there are perspectives in new applications available in the last years, such as contour or texture analysis, and perhaps a combined analysis will provide a more accurate staging of fibrosis.

Moreover, besides the reasonable assessment of fibrosis, CT provides a complete assessment of the liver including the architectural and structural changes such as the vascular and biliary tract changes, and focal and diffuse lesion assessment. For the patients with sustained virologic response it is necessary to redefine a new semiology related to liver remodeling due to regression of fibrosis.

In patients responsive to antiviral therapy, there is a need for more elaborated techniques for the prediction and detection of hepatocellular carcinoma, especially in the context of liver remodeling.

Taking into consideration these advantages, we strongly believe that CT examination provides valuable insights into the extent of the hepatic injuries of cirrhosis and extrahepatic abdominal complication due to portal hypertension and should be used.

OBSTETRIC AND PERINATAL OUTCOMES OF SINGLETONS AFTER SINGLE BLASTOCYST TRANSFER: IS THERE ANY DIFFERENCE ACCORDING TO BLASTOCYST MORPHOLOGY?

A strong correlation between blastocyst morphology and morpho kinetics parameters and implantation has been shown by recent studies. The consequences and effects of assisted reproductive techniques on children's short and long-term health have major impact on the subject and focus on reproduction. The obstetric and perinatal outcome of singletons according to blastocyst morphology has rarely been evaluated. The aim of this observational study is to determine whether a relationship exists between blastocyst morphology and obstetric and perinatal outcomes. A total of 799 singleton clinical pregnancies were analyzed after transfer of a single fresh blastocyst - (day 5) between 2006 and 2013. Blastocysts were divided into four groups based on their morphology on day 5: group 1 = good morphology blastocysts; group 2 = fair morphology blastocysts; group 3 = poor morphology blastocysts and group 4 = early (B1/B2) blastocysts. Obstetric and perinatal outcomes were compared between the four groups of this study. Some confounding variables were adjusted but main obstetric and perinatal outcomes after transfer of blastocysts with poor morphological characteristics were not associated with increased adverse obstetric and perinatal events. Sex ratio was significantly higher in group 1 compared with groups 2, 3 and 4, and in Group 2 compared with Group 3 ($P < 0.001$) even after adjustment ($P < 0.05$) (Céline Bouillon, Noémie Celton1, Sandra Kassem, Cynthia Frapsauce, Fabrice Guérif. Obstetric and perinatal outcomes of singletons after single blastocyst transfer: is there any difference according to blastocyst morphology? *Reprod BioMed Online* 2017; 35(2): 197-207.

PATHOPHYSIOLOGICAL ISSUES INVOLVED IN THE EARLY ONSET OF OSTEOPOROSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS (Abstract). Osteoporosis is a major global health problem, as it is one of the leading causes of disability due to the complications associated with fractures. The mechanisms involved in the onset of osteoporosis are complex; there is significant interference with the immune system, in most cases osteoporosis accompanying the autoimmune joint diseases. Rheumatoid arthritis is the most common systemic articular inflammatory disease, characterized by articular cartilage and periarticular bone damage. Moreover, patients suffering from rheumatoid arthritis associate a decrease in bone mineral density in the axial and peripheral skeleton, posing a high risk of fractures. The discovery of the RANKL/RANK/OPG system led to the elucidation of the pathophysiological mechanisms of metabolic bone diseases by clarifying the communication mechanisms operating between osteoblast and osteoclast. This system led to a better understanding of the molecular processes involved in osteoclastogenesis and thus increased the possibility to intervene in osteoclast formation and to limit exaggerated bone resorption in such metabolic bone diseases as osteoporosis, rheumatoid arthritis, arthrosis, or Paget's disease. **Keywords**: OSTEOPOROSIS, RHEUMATOID ARTHRITIS, BONE RESORPTION, OSTEOCLAST.

Over the last decades, osteoporosis has become one of the major global health problems due to the constant increase in life expectancy, entailing vast, even alarming, health care expenses, with a negative impact on government budgets. It is currently believed that more than 50% of women over age 50 and 13% of men over age 70 will suffer from an osteoporosis-related fracture during their lifetime. It is necessary to improve osteoporosis diagnosis strategies, diagnosis and treatment guidelines, and to extend the scope of evaluation aimed at discovering the disease from its very onset in patients with risk factors, to optimize the management of patients with this condition (1).

BONE MATRIX FORMATION AND REMODELLING

The bone is subject to a continuous remodeling process. Thus, approximately 5-

25% of bone surface is permanently active (1). A bone remodeling cycle is achieved by an active basic multicellular unit (BMU) and has several phases: activation, resorption, reversal and formation. The mechanical or structural destruction stimuli can stimulate osteocytes and thus initiate their apoptosis. Osteocyte biology could also be altered by systemic changes in hormone homeostasis or by corticosteroid action on bone cells. Hauge *et al* (2) highlighted the fact that bone surface lining cells receive signals from the osteocytes and thus influence the microenvironment in order to determine the bone remodeling nucleus. Usually, osteocytes secrete a series of factors, among which TGF-β, which inhibit osteoclast formation. Osteocyte apoptosis stimulation leads to a decrease in the secretion of these factors and, implicitly, could contribute to attracting osteoclast precursor cells. Aguirre *et al* showed that, after a three-day period of immobilization, osteocyte apoptosis preceded the formation of osteoclasts and was followed by approximately two weeks of osteoclastogenesis (3). Li *et al* (4) demonstrated that the osteoblast also plays an important role in the recruitment of osteoclast precursors by secreting more products, the most important of which are MCP-1 (monocyte chemoattractant protein-1) and RANKL (receptor activator of nuclear factor kappa-B ligand). At the level of the active surface, these precursors are transformed into mature osteoclasts, having a role in bone resorption. Osteoclasts are giant polykarion cells, which develop from the line of monocyte/macrophage hematopoietic cells. To this day, they are the only cells capable of destroying the mineralized bone, the dentin and the calcified cartilage (5). After attracting and activating mononuclear precursors, another important step in the formation of mature osteoclasts is their expression of M-CSF receptor c-fms, and its activation with the ligand. Thus, proliferation is induced and the next phase commences, i.e. the expression of the receptor activator of nuclear factor kappa B (RANK). The presence of the ligand for RANK, RANKL is essential to ensure the formation and fusion of multinucleated cells. RANK signaling determines the activation of transcription factors with a major role in osteoclastogenesis. These include protein-1, NF-kB or NFAT (nuclear factor of activated T-cells). Several proteins, including cathepsin K, calcitonin receptor (CTR), TRAP (tartrate-resistant acid phosphatase) and integrin receptors are expressed on the surface of mature osteoclasts (5). To maintain the acidity of the microenvironment necessary for bone resorption, the osteoclasts are attached very tightly to the matrix by means of integrins. The degradation of the organic matrix is achieved by many enzymes, including cathepsin K, TRAP and matrix metalloproteinases MMP-9.

THE RANKL/RANK/OPG SYSTEM

The discovery of the RANKL/RANK/OPG system led to the elucidation of the pathophysiological mechanisms involved in metabolic bone diseases by clarifying the communication mechanisms between osteoblast and osteoclast. It also contributed to the development of innovative therapies for osteoporosis, such as human antibody RANKL (6). By clarifying the molecular processes of osteoclastogenesis, the discovery of RANKL and of its receptors, RANK and OPG (osteoprotegerin), increased the possibility to intervene in the formation of osteoclasts and in limiting excessive bone resorption in such metabol-

ic disorders as osteoporosis, rheumatoid arthritis, arthrosis or Paget's disease (1). The first discovered protein belonging to this system was OPG, so called due to its bone-protective effects, and its ability to inhibit osteoclast development and activation. To date, this is its most important role. Osteoprotegerin is part of the TNF receptor superfamily; it is expressed both at bone-level, as well as in many tissues such as kidney, stomach, heart, lung, brain, bowel, thyroid gland, or spinal cord. Following these discoveries, some researchers (1) attributed an important role to this protein in endothelial cell survival. Moreover, in 2006, Rasmussen discovered the involvement of OPG in vascular calcification.

The next protein belonging to this system was represented by RANKL, eventually named after the initials of the four researchers who identified it. It is a protein from the TNF superfamily and is expressed in many tissues, essentially in the bone (preosteoblast/stromal cells, but also in activated T cells), kidney, lung, heart, brain, liver, skeletal muscle, bowel, placenta, mammary tissue, thymus, spleen and testicles. Even though the main role of RANKL is linked to bone remodeling, its extended distribution throughout the body indicates its involvement in many other functions. RANKL is present in tissues in three isoforms. The first two, RANKL 1 and RANKL 2, are type II transmembrane proteins, while the third, RANKL3, is a soluble protein. It is assumed that RANKL3 is sectioned from the transmembrane form by TACE (metalloproteinase, enzyme that converts TNFα). The third member of this system is RANK, a protein which, like OPG, belongs to the TNF receptor superfamily. RANK is a type I transmembrane protein. It is most commonly encountered in osteoclasts and dendritic cells, but it is also expressed in all other tissues in which RANKL can be found as well (7). Mice that lack the RANK protein have similar phenotypes to those that cannot express RANKL, the latter presenting osteopetrosis and lacking dental eruption and lymph nodes. RANKL binds to the extracellular domain of RANK and, with the help of TRAF6 (TNF receptor associated with factor 6), can induce the RANK signaling pathway.

Furthermore, Rauner *et al* (8) showed that there are many mediators that can lower TRAF levels, the most important of which are A AP-1, NF-Kb, NFATc1 (nuclear factor of activated T-cells), but also the mitogen-activated protein kinase pathway (MAPK), including JNK (c-Jun N-terminal kinase), p38 stress kinase, and ERK (extracellular signal–regulated kinase). Leibbrandt and Penninger (9) described a series of local and systemic factors that influence the expression of OPG and RANKL. Among such factors that stimulate the expression of RANKL, they describe the parathyroid hormone, glucocorticoids, 1,25(OH) vitamin D, IL-1, 6, 8 and prostaglandin E. The category of factors involved in stimulating the expression of OPG includes estrogens, INF-γ, bone morphogenetic protein 2 and TGF-β.

Both in physiological as well as in pathological conditions, many cytokines and chemokines are involved in bone remodeling. Lorenzo *et al* (10) described, on the one hand, pro-inflammatory cytokines, that stimulate the expression of RANKL on the surface of the osteoblast, or stimulate the formation and activation of osteoclasts and, thus, increase the loss of bone mass. On the other hand, they described cyto-

kines acting as inhibitors of osteoclastogenesis by blocking RANKL signaling, both directly and indirectly, thus reducing bone resorption. The proresorbtive cytokines are IL-1, 6, 7, 15 and 17, while the antiresorptive ones are IL-4, 5, 10, 12, 13, 18; however, interferon α, β and γ plays the same role.

Unlike cytokines, little is known nowadays about the role played by chemokines in regulating bone mass. Binder *et al* (11) showed that C-C chemokine receptor type 2 (CCR2) plays an important role in maintaining bone mass under physiological and pathological conditions. They demonstrated that CCR2 induces the expression of RANK on osteoclast precursor cells, thus increasing the susceptibility to RANKL-induced osteoclastogenesis.

The impact of inflammatory diseases on bone metabolism has been studied extensively, and a significant damage of osteoblast and osteoclast coupling has been noticed. Cytokines, including TNFα, are released in both local and systemic inflammation, which could lead to bone loss by the direct activation of osteoclast differentiation and activity.

Yoshitake *et al* (12) showed the important role played by IL-6 in osteoclast differentiation. It increases the expression of RANKL on osteoblasts and determines the suppression of the degradation of the kB factor and the activation of JNK, determining the direct stimulation of osteoclast differentiation by activating the RANK/RANKL/OPG pathway.

BONE LOSS IN RHEUMATOID ARTHRITIS

Both juxta articular osteoporosis and generalized osteoporosis can be found in rheumatoid arthritis, these patients being at high risk for fracture. It appears that periarticular osteoporosis is predominantly mediated by local mechanisms, related to those of rheumatoid synovitis. Identifying juxta articular osteoporosis is one of the earliest radiological signs in rheumatoid arthritis. Generalized osteoporosis is also detected in rheumatoid arthritis, with a high enough frequency, its etiology being considered multifactorial. T cell involvement, resulting in rheumatoid nodule formation, as well as B cell activation with autoantibody production, is encountered in this disease as well. The microscopic examination of the synovial tissue of inflamed joints highlighted a non-specific inflammatory infiltrate, containing T cells, B cells, neutrophil, macrophage, and mast cells. Raza *et al* (13) showed that inflammatory response is directed by a complex network of cytokines. The main role is held by the macrophages secreting proinflammatory cytokines in the inflamed synovial joints. As the disease progresses, the cellular basis of inflammatory response changes. In the early stages of the disease, the key role seems to be held by T cells.

Osteoporosis, both systemic and local, through periarticular bone loss adjacent to inflamed joints, is very common in patients with rheumatoid arthritis. These changes were due to an increased level of proinflammatory cytokines at local and circulatory levels. The activation of $CD4^+$ cells has been shown to occur in the inflamed synovium, the predominant immune cell population at this level, the stimulation of RANKL production supporting osteoclastogenesis thus taking place (14). In addition, the *in vivo* systemic activation of T cells has been shown to result in RANKL-mediated osteoclast differentiation and bone loss.

Kong *et al* (15) demonstrated that the administration of exogenous OPG in rats with adjuvant arthritis neutralizes RANKL and prevents bone loss and cartilage destruction. An increase in RANKL was noticed in patients with rheumatoid arthritis, which was associated with increased osteoclastogenesis. OPG levels are low in the synovial fluid of patients with rheumatoid arthritis, this being valid only for inflamed joints. These low OPG levels could limit the possibility to counterbalance the RANKL effects of stimulating osteoclastogenesis in join inflammation. Moreover, the same authors also discovered that the *in vitro* administration of exogenous OPG could inhibit IL-17, a proinflammatory cytokine with significant effects in stimulating osteoclastogenesis in rheumatoid arthritis. This could be a useful therapeutic option in severe forms of rheumatoid arthritis.

It appears that the loss of juxta-articular bone mass is based on a significant reduction of the cancellous bone at the level of the bone metaphysis adjacent to the inflamed joints. The bone geodes appearing alongside the inflamed joints are also part of the arthritic process of the disease.

The pathophysiological mechanisms involved in systemic osteoporosis in rheumatoid arthritis are multifactorial. The factors described to be involved in this process are: the systemic effect of the inflammation, drugs (such as corticosteroid therapy), DMARDs therapy, immobility, nutritional deficiencies, endocrine changes in menopause, weight loss. The activity of the diseases contributes independently to axial bone loss. This can be noticed especially at the level of the proximal femur. About the involvement of inflammatory cytokines, a significant increase in IL-1 and IL-6 serum levels has been noticed, many studies demonstrating that these cytokines determine the suppression of bone formation and accelerate bone resorption. The involvement of immobilization in bone loss has been demonstrated by many studies, showing a close link between functional capacity and axial BMD, the effects being more significant in the femur than in the vertebrae.

Approximately 25% of patients with rheumatoid arthritis suffer from osteopenic low bone mineral density, both at spine and hip-level, before the onset of the disease, and before initiating therapy, while 10% of such patients suffer from osteoporosis. Given that the prevalence of low bone mass is already present at the onset of the disease, this led to the conclusion that patients with rheumatoid arthritis have a high risk of developing complications determined by systemic bone loss. Another explanation is related to the presence of a low level of inflammation which can precede the onset of clinical symptoms in rheumatoid arthritis for a long period of time.

CONCLUSIONS

In our opinion, an impaired balance between bone resorption and bone formation mechanisms contributes to juxta-articular bone loss. This appears to be mediated by the increased cytokine and prostaglandin production in, by the synovium and bone marrow. Generalized bone loss is frequently encountered in patients with rheumatoid arthritis, resulting in increased risks of falling and fracture. Local bone destruction in rheumatoid arthritis could determine joint instability and can often lead to reconstruction surgery or even joint prosthesis.

About systemic bone loss in the context of rheumatoid arthritis, an increased risk of

fractures of the hip, spine and wrist has been noticed, the mechanisms involved in systemic osteoporosis in rheumatoid arthritis being multifactorial.

A "RARE" CAUSE OF PERICARDIAL EFFUSION–CASE REPORT (Abstract): Although tuberculosis classically affects the lungs, lymphatic and hematogenous dissemination, as well as direct invasion of the pericardium from the adjacent pleura make *Mycobacterium tuberculosis* the most frequent cause of acute pericardial effusion in developing countries. We present the case of a 68-year-old patient presenting with acute cardiac failure due to large pericardial effusion, a week after undergoing drainage of a facial subcutaneous abscess. Pericardiocentesis followed by video-assisted thoracoscopic pericardial window were performed. Blood cultures were repeatedly negative, but the biochemical analysis of the pericardial fluid showed low glucose concentration and high protein levels, elevated adenosine deaminase and lactate dehydrogenase levels. Although bacterioscopy and pericardial fluid cultures were negative, we made a presumptive diagnosis of tuberculous fibrinous pericarditis and initiated appropriate therapy with rifampin, isoniazid, pyrazinamide, and ethambutol, with favorable clinical outcome. Our diagnosis was confirmed 22 days later, when the Mycobacteria Growth Indicator Tube cultures were positive for *M. tuberculosis*. Although tuberculosis is a rare cause of pericarditis in the Western world, in a country endemic for tuberculosis (such as Romania), the tuberculous etiology of fibrinous pericarditis should not be overlooked. **Keywords:** EXTRAPULMONARY TUBERCULOSIS, FIBRINOUS PERICARDITIS, PERICARDIAL TAMPONADE, VIDEO-ASSISTED THORACOSCOPIC PERICARDIAL WINDOW, MYCOBACTERIA GROWTH INDICATOR TUBE.

Classic tuberculosis (TB) affects the lungs, but forms of extrapulmonary tuberculosis located in the genitourinary tract (1, 2), central nervous system (3), gastrointestinal tract (4), and skeletal system (5) have also been described. Tuberculous pericarditis is a severe form of extrapulmonary TB, being associated with a high 6-month mortality rate (17-40%) (6, 7). The incidence of TB pericarditis ranged from less than 4% in Western countries to 50-90% in developing regions, where tuberculosis is endemic (7, 8, 9). Although Romania remains endemic for tuberculosis, the number of extrapulmonary TB cases has gradually decreased during the past years, but 40-50 cases of TB pericarditis are still annually reported (10).

The most frequent clinical presentation of TB pericarditis is congestive heart failure (7). One of the most feared complications of TB pericarditis is constriction, which usually occurs within 6 months in 50% of cases in the absence of targeted

anti-TB therapy (6, 7). This rate has been reduced to 17-40% with the help of aggressive anti-TB treatment and corticosteroid therapy (6). A noteworthy limitation of TB chemotherapy is the poor penetration of antibiotics into the pericardium (11).

CASE REPORT

A 68-year-old male patient was admitted to an otorhinolaryngology clinic for drainage of a frontal abscess of unknown etiology. A week after discharge, the patient developed fever (38°C) accompanied by chills and was referred to the infectious diseases department. Despite aggressive antibiotic therapy, he developed dyspnea on minimal exertion, palpitations, chest pain and exercise-related liver pain and was transferred to the local cardiology clinic.

The clinical exam revealed tachypnea, tachyarrhythmia (113 bpm), normal blood pressure, and right-sided heart failure. Routine laboratory evaluation showed inflammation (erythrocyte sedimentation rate 100 mm/hr., fibrinogen 948 mg/dL, elevated C reactive protein), thrombocytosis (663,000/mm^3) and cardiac enzymes within normal range. Electrocardiogram revealed paroxysmal atrial fibrillation, managed with amiodarone and carvedilol. A throat swab culture revealed *Candida albicans* infection for which he received appropriate local treatment.

Echocardiography revealed circumferential pericardial effusion (34 mm) with fibrinous material and pericardial thickening (0.99 cm). Chest X-ray (radiography) showed pulmonary congestion and enlarged cardiac silhouette (fig. 1). The performed chest computed tomography (CT) (fig. 2, 3) detected multiple infracentimetric aortopulmonary lymph nodes with peripheral enhancement, but no active pulmonary or bone lesions. Although initial and repeated blood cultures were negative, the patient continued to present fever although he was on antibiotic therapy and nonsteroidal anti-inflammatory drugs.

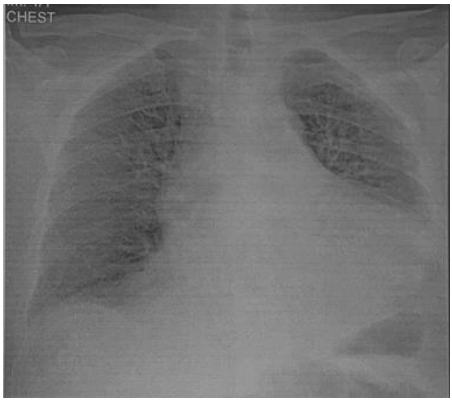

Fig. 1. Chest X-ray - enlarged cardiac silhouette, pulmonary congestion

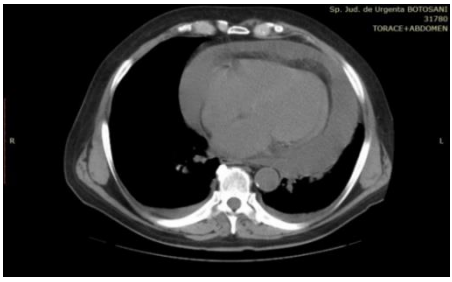

Fig. 2. Chest CT – pericardial effusion (maximum thickness 33 mm)

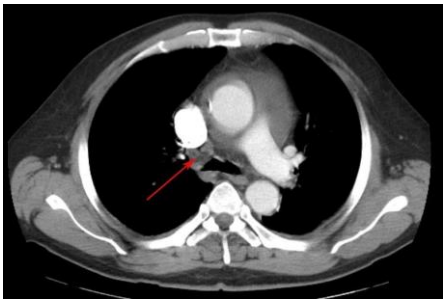

Fig. 3. Contrast enhanced chest CT – enlarged lymph nodes with peripheral enhancement

The patient began to show signs of incipient cardiac tamponade so he was transferred to the thoracic surgery department where pericardiocentesis and drainage of 100 mL serous fluid were performed. Pericardial fluid bacterioscopy and cultures were negative. Cytology was negative for tumor cells. Biochemical analysis revealed microscopic lymphocytic inflammatory reaction with high protein levels (46.8 g/L), high adenosine deaminase (ADA) - 71 U/L, high lactate dehydrogenase (LDH) - 849.2 U/L and low glucose (67.4 mg/dL) levels.

As the patient showed no clinical improvement after 2 days of conservative therapy he underwent a video-assisted thoracoscopic pericardial window performed on the left side. Pericardial biopsy confirmed our previous diagnosis of fibrinous pericarditis. A control chest X-ray was performed after the procedure (fig. 4).

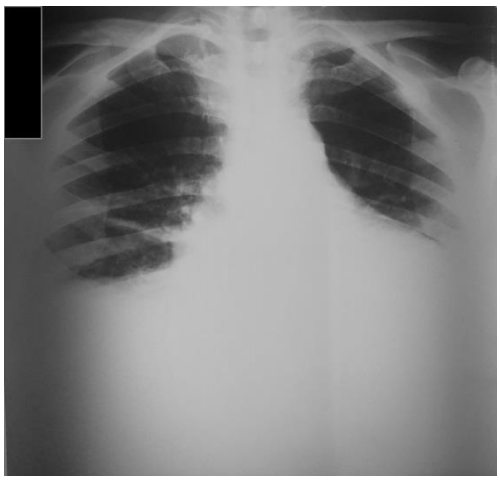

Fig. 4. Chest X-ray – bilateral pleural effusion, enlarged cardiac silhouette

We decided to initiate anti-TB chemotherapy with rifampin, isoniazid, pyrazinamide and ethambutol along with oral corticosteroids (prednisone). The diagnosis was confirmed after 22 days, when the *Mycobacteria Growth Indicator Tube* (MGIT) cultures detected *M. tuberculosis* susceptible to rifampin, isoniazid and ethambutol. The outcome was favorable with no evidence of constriction during the 4-month follow-up.

DISCUSSION

Our patient was admitted for rapidly progressive heart failure due to massive pericardial effusion. The following investigations were performed: chest X-ray (class I), inflammation marker panel (class I) and CT (class IIa). Although he did not meet the criteria for acute pericarditis (no pericarditic chest pain and friction rub, no ST elevation or PR depression), the current guidelines recommend managing pericardial effusions with positive inflammatory markers as pericarditis (7).

Our patient presented rapid clinical and biological decline after the drainage of a subcutaneous frontal abscess, so systemic staphylococcal or streptococcal infection with pericardial involvement was a possible cause of his current condition. Patient medical history was negative for TB and the CT scan did not detect any active pulmonary or bone lesions. However, he presented significant pericardial thickening, massive effusion with frond-like projections, and typical lymph node enlargement (hypodense center), all suggestive of TB etiology (7).

Since a bacterial etiology of the pericardial disease was suspected and our patient associated early signs of cardiac tamponade, pericardiocentesis (class I) (7) and drainage of 100 mL of serous fluid were performed.

Tuberculous pericardial effusions are usually cloudy and serosanguineous (12).

The detection of acid-fast bacilli during microscopic assessment is diagnostic for TB but reported in only 40-60% of cases (12). Although in our patient the fluid analysis was negative for acid-fast bacilli, it documented lymphocytic inflammatory reaction with very high protein levels, both recognized features of tuberculous pericardial effusions (12). Increased pericardial interferon-gamma and ADA levels are associated with TB pericarditis (7,12). In our case, pericardial ADA levels were >40 U/L (a cut off value with 93% sensitivity and 97% specificity in diagnosing TB pericarditis) (12).

Per current guidelines, subjects with relapsing cardiac tamponade, repeated accumulation of pericardial effusion and those who do not improve with drug therapy should undergo surgical drainage. Pericardial biopsy is a class IIb indication for suspected TB pericarditis (7). As our patient’s clinical condition did not improve despite optimal drug treatment, we decided to perform a video-assisted thoracoscopic pericardial window.

The definite diagnosis of TB pericarditis requires the detection of *M. tuberculosis* in pericardial fluid or tissue through polymerase chain reaction (PCR) or cultures (6,7). Microbiological diagnosis can be augmented through cultures from extracardiac sites (pleural fluid, lymph nodes and sputum) (13). A possible diagnosis is based on successful response to TB chemotherapy or high ADA, unstimulated interferon-gamma or lysozyme levels in the pericardial fluid (7). Only 17% of cases meet the criteria for definite TB pericarditis (6). A study reported interferon-gamma measurement in the pericardial fluid as the best diagnostic tool, especially combined with ADA and cytology of pericardial effusion (13). Our patient’s CT scan was negative for active pulmonary lesions and superficial adenopathies, suitable for biopsy. The tuberculin skin test is not recommended in adults and we did not perform it in our patient. The guidelines recommend the use of interferon-gamma release assays in patients with probable TB, but the results are less specific in countries where tuberculosis is endemic (7).

The initiation of empiric anti-TB treatment in endemic regions is allowed as soon as other causes of pericardial effusion have been excluded (trauma, autoimmunity, cancer, uremia, purulent pericarditis), but it is not justified in countries where TB is not endemic and there is no clear evidence supporting the tuberculous etiology. Prevention of pericardial constriction requires 6 months of standard combined anti-TB treatment (class I). Intrapericardial urokinase reduces the risk of constriction. High-dose prednisolone can reduce the risk of developing constriction and has a class IIb recommendation in immunodeficiency virus-negative human subjects (7).

Our diagnosis of tuberculosis was based on clinical suspicion (endemic area for TB), echocardiographic and CT findings (pericardial thickening, fibrinous material) and high pericardial ADA and protein levels. The diagnosis was later confirmed by a positive response to empirical anti-TB treatment and positive MGIT cultures. Our patient should have regular follow-up as part of the screening for constrictive pericarditis, although he showed no evidence of constriction after 4 months of anti-TB treatment.

CONCLUSIONS

This case report proves that in a country endemic for tuberculosis, the differential

diagnosis of pericarditis should include *Mycobacterium tuberculosis* as one of the most frequent causes of pericardial effusion. We consider video-assisted thoracoscopic pericardial window along with pericardial and pleural biopsies to be valuable diagnostic and therapeutic tools for tuberculous pericarditis. Because of the high mortality rates associated with this condition, we chose to initiate aggressive anti-TB chemotherapy even in the absence of a definite diagnosis.

PROGNOSTIC VALUE OF RIGHT VENTRICULAR FUNCTION ASSESSED BY ECHOCARDIOGRAPHY IN PATIENTS PRESENTING WITH A FIRST ACUTE ST ELEVATION MYOCARDIAL INFARCTION TREATED BY PRIMARY PCI (Abstract) **Aims**: Informations regarding the prognostic value of right ventricular function changes in the setting of a first acute ST elevation myocardial infarction irrespective of the site of the necrosis and of the left ventricular systolic function are scarce. Purpose of the study was to assess the relation between parameters reflecting global and systolic right ventricular function assessed by conventional, speckle tracking and three-dimensional echocardiography and in hospital major cardiac events (MACE). **Material and methods:** We have prospectively analyzed a cohort of 44 consecutive patients (mean age 62,71 years, 70.5 % males) presenting with a first STEMI (2,3 % Topol 1, 38 ,6 % Topol 2, 20,6 % Topol 3, 31,8 % Topol 4, 6,8 % Topol5) treated by primary angioplasty. Patients with previous history of cardiac or pulmonary diseases were excluded. All patients underwent during hospitalization conventional 2D echocardiography and special techniques (2D speckle tracking echocardiography and also 3D echocardiography) RV global function was quantified by RV myocardial performance index (RV MPI) determined by PW Doppler ,whereas RV systolic function was studied using regional parameters like TAPSE , pulsed Doppler S wave and RV free wall 2D strain and global parameters like RV fractional area change (RV FAC) or RV ejection fraction (RVEF) determined by 3D echocardiography . LV systolic function was described by LV ejection fraction (LVEF). The combined endpoint of major adverse cardiovascular events **(**MACE**)** was defined by all cause mortality, reinfarction, need for revascularization and occurrence of heart failure during hospitalization. The association between MACE and RV functional parameters was assessed by bivariate correlation analysis followed by binary logistic regression. **Results**: Initially, regardless of the site of necrosis, the only RV functional parameter correlated with MACE was RV MPI (OR 9.17; 95% CI: 1.03 -83.7). After adjustment for LVEF all RV functional parameters were correlated with MACE: TAPSE (OR: 1.83; 95% CI : 0.41- 8.23), RV MPI (OR: 8.07; 95% CI : 0.9- 72.07), RVFAC (OR: 1.22; 95% CI : 0.25- 5.98) , RV free wall strain (OR : 1.04; 95% CI : 0.21- 5.08) , S wave (OR: 2.46 ; 95% CI : 0.14- 42.82), RVEF (OR: 0.83 ; 95% CI : 0.20- 3.43). **Conclusions:** Our study reveals that RV functional parameters are predictive for in hospital MACE beyond LV systolic function and regardless of the culprit coronary artery. Among these parameters, RV MPI seems to have the greatest predictive value for short term MACE in STEMI patients. **Keywords:** PRONOSTIC, RV FUNCTION, ECHOCARDIOGRAPHY.

The prognosis of patients presenting with acute myocardial infarction depends on many clinical, biological or imagistic factors. Parameters reflecting left ventricular systolic or diastolic function measured by echocardiography during hospitalization after an acute myocardial infarction are strongly related with the occurrence of adverse events in short and long term follow up studies (1-3). Accordingly, left ventricular functional noninvasive assessment has become indispensable at discharge in patients with acute myocardial infarction.

In clinical practice, the right ventricle has been initially called the forgotten chamber (4) because most studies have evaluated the prognostic importance of LV function. In the last five years, based on the increased number of papers describing RV functional assessment (5, 6) or the prognostic significance of RV function in many diseases (7-9), RV has been no more longer called the forgotten chamber but rather an incompletely understood cavity, still not a desirable state (10).

The importance of right ventricular function assessed in the setting of an acute myocardial infarction is not very good defined now. Echocardiographic assessment of right ventricular function, the most available imagistic method, consists of an integrative approach by measuring right ventricular size and function (5,6). In acute myocardial infarction with inferior localization, right ventricular involvement assessed through the fractional area change (RV-FAC), a 2D echocardiographic parameter describing RV global systolic function, has been defined as a strong predictor of complications and in hospital mortality (11). RV dysfunction is associated with adverse prognosis in post-acute myocardial infarction patients with moderate to severe LV dysfunction (12). Recent data suggests that RV functional involvement, evaluated through 2D and speckle tracking echocardiography in the first 48 hours after coronary angioplasty, is associated with strong prognostic informations regarding the occurrence of major cardiac events on long term follow up (13).

Informations regarding the prognostic value of right ventricular function changes in the setting of a first acute ST elevation myocardial infarction irrespective of the site of the necrosis and of the left ventricular systolic function continues to be scarce and have been less studied.

MATERIAL AND METHODS

From March 2015 to April 2016, 44 consecutive patients presenting with a first acute STEMI and treated with primary PCI within the first 12 hours were included and screened prospectively. Patients were treated per the national protocol, which is driven by the recommendations included in the most recent guidelines (14). This protocol provides that every patient with ST elevation myocardial infarction which presents in the first 12 hours should be transferred as soon as possible to a center capable of primary PCI. Patients are receiving thrombolysis if transfer time to the tertiary center exceeds 2 hours. ST elevation myocardial infarction was diagnosed on criteria included in the universal definition of myocardial infarction: new or presumably new ST segment elevation or new left bundle branch block on ECG in addition with rise and fall of cardiac biomarkers with or without symptoms of ischemia. In addition, all patients underwent conventional echocardiography and special echocardiographic techniques. Patients with previous history of cardiac and pulmonary diseases were excluded from the study.

The study was approved by the human

research committee of our hospital, and informed consent was obtained from all subjects.

Echocardiographic images were obtained with patients in the left lateral decubitus using Vivid Q and Vivid E9 machines (General Electric-Vingmed, Horton, Norway) with a 3.5 MHz transducer. Standard 2D echocardiography was performed in addition to 2D speckle echocardiography at discharge; also, all patients underwent three-dimensional echocardiography with a dedicated transducer. All images were obtained at a rate of 50-70 frames/s and three consecutive cardiac cycles were saved in digital format. Data analysis was performed offline by an experienced observer using a dedicated software (EchoPack BT12 GE Vingmed), to assess right and left ventricular function. The reference limits of all echocardiographic parameters were defined per the current adopted international guidelines (6).

LV functional assessment was defined by measuring LV ejection fraction through 2D echocardiography. The LV end-systolic volume (LVESV) and LV end –diastolic volume was determined in the apical 4 chamber and 2 chamber view and LVEF was calculated using the biplane Simpson method (6). RV functional assessment was made using the multiparametric approach as recommended by the current guidelines (5,6). RV global function was quantified by RV myocardial performance index (RV MPI) determined by PW Doppler, whereas RV systolic function was studied using regional parameters like tricuspid anular plane systolic excursion (TAPSE) , pulsed Doppler S wave velocity and RV free wall 2D strain and global parameters like RV fractional area change (RV FAC) or RV ejection fraction (RVEF) determined by 3D echocardiography.

The RVMPI has been obtained by the pulsed Doppler method, using the parasternal short axis view, where ejection time was measured at the RV outflow (time from the onset to the cessation of the flow) and the apical 4 chamber view where the tricuspid valve closure-opening time was obtained placing PW sample at the tips of the tricuspid valve. Results represent the average of measurements done in 5 cardiac cycles. Based on the idea that data is taken from different images, one most therefore attempt to use beats with similar R-R length for recording accurate data (fig. 1a, 1b). RV MPI represents the ratio between the difference tricuspid valve closure-opening time and the ejection time divided by the ejection time.

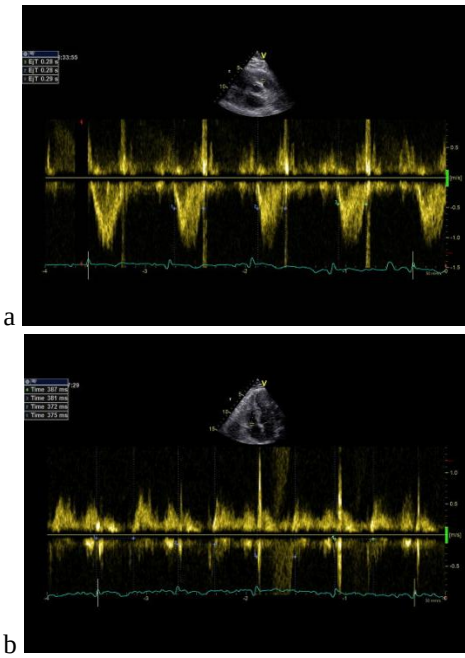

Fig. 1.
a. Measuring RV ejection time at the RV outflow; **b.** Measuring tricuspid valve closure –opening time in the apical 4 chamber view

RV systolic function was studied using regional parameters like TAPSE, tissue pulsed Doppler S wave velocity and RV free wall strain. TAPSE was measured in the 4-chamber view, placing the M mode cursor through the tricuspid annulus and the total displacement of the RV base from end- diastole to end-systole was measured. S wave velocity, representing the longitudinal velocity of the RV free wall, was measured in the 4-chamber apical view, using pulsed tissue Doppler, high lightening the RV free wall. The pulsed Doppler sample volume is placed on the tricuspid annulus or in the middle of the basal segment of RV free wall. Specific software generates velocity profiles over the cardiac cycle, S wave representing the highest systolic velocity after the iso volumic contraction period (fig. 2). Peak systolic longitudinal strain of the RV free wall was measured in the RV focused 4 chamber view, using speckle tracking analysis, with LV dedicated software, applied to RV. Strain analysis was performed offline by an experienced observer using Q-Analysis package. Briefly, the endocardium was manually traced at end-systole and the region of interest (ROI) was adjusted to include the whole myocardial wall but to exclude the pericardium. The reference point of each cardiac cycle was placed at the beginning of the QRS complex. Peak systolic longitudinal strain was determined as the average of the strain displayed by the system in the three segments of the RV free wall (basal, medial, apical). Strain analysis was feasible in all segments obtained from the 44 patients included in the study (fig. 3).

RVFAC was measured by tracking the RV end diastolic area and the RV end systolic area in the apical RV focused view, using the formula RVFAC=RVEDA-RVESA/RVEDAx100.

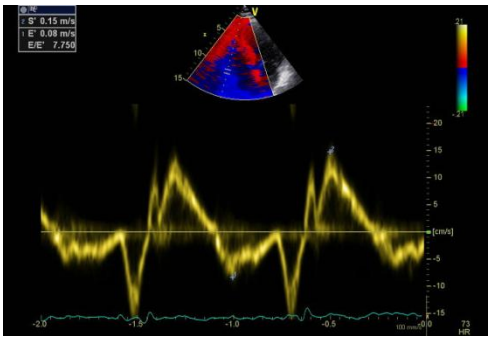

Fig. 2. Measuring S wave velocity using pulsed Doppler in the apical 4 chamber view

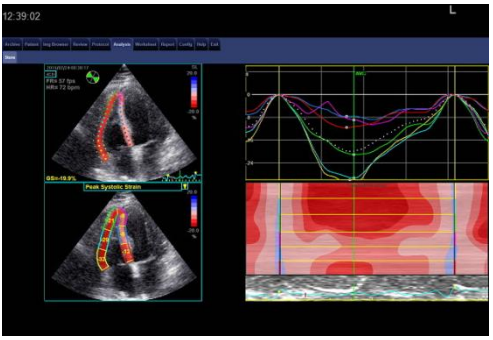

Fig. 3. Measuring free wall RV longitudinal strain by speckle tracking method

RVEF, as a measure of global systolic function was determined using three-dimensional echocardiography, requiring a dedicated multibeat 3D acquisition, with minimal depth and sector angle (for a temporal resolution > 20–25 volumes/sec) that encompasses entire RV cavity Automatically identified timing of end-diastole and end-systoles were carefully verified, whereas myocardial trabeculae and moderator band were included in the cavity. RVEF was measured offline by an experimented observer using dedicated TomTec software (fig. 4).

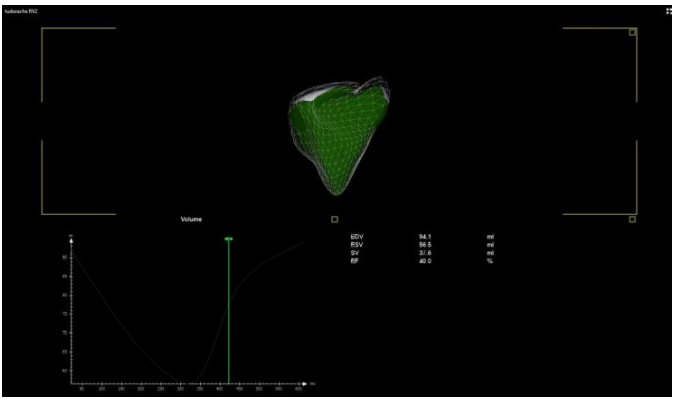

Fig. 4. Measuring RVEF by three-dimensional echocardiography, using TomTec software

Continuous data are presented as mean +/- standard deviation and categorical data are presented as frequencies and percentages. Chi-square and independent samples t test were used to validate the statistical significance between proportions and means respectively. The primary aim was to assess the association between RV function and adverse events. The combined endpoint of major adverse cardiovascular events **(**MACE**)** was defined by all-cause mortality, reinfarction, need for revascularization and occurrence of heart failure during hospitalization. The association between MACE and RV functional parameters was assessed by bivariate correlation analysis (Spearman correlation coefficient) followed by univariate binary logistic regression. Statistical analysis was performed using IBM *SPSS 20.0* at a statistical significance threshold of $p < 0.05$.

RESULTS

A total of 44 consecutive STEMI patients were studied. Mean age was 62,73+/- 13.42 years and most of the patients were men (70.5%). Regarding myocardial infarction localization on the electrocardiogram 2,3 % patients were Topol 1, 38 ,6 % patients were Topol 2, 20,6 % patients were Topol 3, 31,8 % patients were Topol 4 and 6,8 % patients were Topol 5. From the study population, 7 patients (15.9%) had right ventricular myocardial infarction based on the presence of ST elevation in the right precordial leads. A total of 27 patients (61.36%) suffered from anterior myocardial necrosis involving the left descending artery, whereas the remaining had non-anterior myocardial infarction with culprit lesions on the circumflex or on the right coronary artery. During in hospital follow up, major adverse cardiac events (MACE) defined as all cause mortality , reinfarction, need for revascularization or signs and symptoms of heart failure occurred in 12 patients (27.3 %).

Tables 1 and 2 summarize the clinical, electrocardiographic and echocardiographic characteristics and the differences between patients who reached the composite end and patients who remained event free. Average length of hospitalization was 8.7±3.77 days for patients with MACE respectively 7.18±2.19 days for patients without MACE. Simptom to balloon time was nonsignificant statistically between the two groups (MACE and MACE free)

467.14±245.473 minutes respectively 624.19 ± 906.064 minutes. The same situation was encountered regarding the door to balloon time 90±120 minutes for MACE patients and 148.32 ± 509.761 minutes for MACE free patients. Mean values of LVEF, TAPSE, S wave velocity, RV longitudinal strain, RV FAC, RVEF and RV MPI of the study group were: 44.49 %+/-8.67, 19.6 mm+/-4.03, 0.134 m/sec+/-0.027, 21.14 %+/-12.74, 42.1%+/-8.81, 44.98 %+/-9.31 and 0.55+/-0.18 respectively, also without statistically significance.

Regarding RV function and association with outcome, statistical analysis was performed for all echocardiographic measurements recorded during the in-hospital echocardiogram. Initially, regardless of the site of necrosis, the only RV functional parameter correlated with MACE was RV MPI (OR 9.17; 95% CI of OR: 1.03 -83.7; p=0.037). After adjustment for LVEF, all the studied echocardiographic parameters showed statistical significance: TAPSE (OR : 1.83; 95% CI : 0.41- 8.23; p<0.001), RVFAC (OR : 1.22; 95% CI : 0.25- 5.98; p<0.001) , RV free wall strain (OR : 1.04; 95% CI : 0.21- 5.08;p=0.024) , S wave (OR : 2.46 ; 95% CI : 0.14- 42.82 ;p=0.004; p=0.001) and RVEF (OR : 0.83 ; 95% CI : 0.20- 3.43) (tab. III).

DISCUSSION

In the past, the clinical importance of RV function has been underestimated. The important finding of this ongoing study is that right ventricular function assessed during hospitalization in patients with acute myocardial infarction treated per the current guidelines could have additional prognostic information, in addition to the classic risk factors (15). Quantifying RV function is more difficult compared to the left ventricle and needs a multiparametrical approach with conventional 2D echocardiography and newer techniques like speckle tracking echocardiography or three-dimensional echocardiography. RV systolic and diastolic function can be expressed by variable echocardiographic measures including TAPSE, RVFAC, RV MPI, RV longitudinal strain, S wave velocity, or, the most complete parameter, RVEF. In our research, all these parameters were predictors of the combined endpoint of major adverse cardiovascular events, defined by in hospital all-cause mortality, reinfarction, need for revascularization and occurrence of heart failure. From the above-mentioned measurements, the one describing global RV function, the RVMPI, correlated with MACE irrespective of LV function. The other parameters quantified regional or global RV systolic function like TAPSE, S wave velocity or RVFAC or RVEF gained statistical significance after adjustment for LV function. RVMPI obtained by dividing the sum of the isovolumic contraction and

relaxation time to the RV ejection time represents o measure of global RV function. It is reproducible but is load dependent and unreliable when right atrial pressure is elevated like in cases of RV infarction, when it is inappropriately small or pseudo normalized (16). RVMPI has been studied in acute right ventricular myocardial infarction where it is used to quantify right ventricular dysfunction and assess improvements in RV function (17). Measurement of this parameter or determining its prognostic significance in the setting of a first acute myocardial infarction irrespective of localization hasn't been on our knowledge studied. In our study, the RVMPI was initially, regardless of the site of necrosis, the only RV functional parameter correlated with MACE (OR 9.17; 95% CI of OR: 1.03 -83.7).

TAPSE is maybe the most frequently used measurement to assess RV function and reflects the longitudinal systolic excursion of the lateral tricuspid valve annulus, which may not fully reflect RV contractility, as it is a measure of segmental systolic function. In the GISSI -3 echo sub study in acute myocardial infarction patients, TAPSE was significantly associated with LVEF and as LVEF recovered over time, RV function improvement was also noticed (18). In the study by Antoni et al (13), TAPSE proved strong association with adverse events on 24 months follow up in acute myocardial infarction treated by primary PCI. The S wave velocity determined by pulsed tissue Doppler S is easy to measure, reproducible, reflecting regional RV systolic function, but have not been studied like TAPSE in the setting of acute coronary syndromes. In our study both TAPSE and S wave velocity were associated with in hospital occurrence of adverse events after adjusting for LV function (OR: 1.83; 95% CI: 0.41- 8.23 respectively OR: 2.46; 95% CI : 0.14- 42.82).

Strain is a novel technique that permits angle independent measurement of longitudinal deformation of the RV , which represents the main mechanism of RV function, because 80% of the stroke volume is generated by the longitudinal shortening of the RV free wall (19) RV strain excluding the interventricular septum has been recently and for the first time demonstrated in the study by Antoni et al to have independent predictive value for adverse events in AMI patients, the same fact being demonstrated in our research but regarding short term follow up (13).

RVFAC is the most commonly used parameter to assess global systolic RV unction, but has inherent limitations because it is experience dependent and reproducibility is often poor. In AMI patients with LV dysfunction, characterized by LVEF <40% Anavekar et al (12) and Zornoff et al (11) highlighted that RV function, expressed through RVFAC is poor correlated with LV function and is independently associated with an increased risk of mortality and heart failure (OR: 1.22; 95% CI: 0.25-5.98) . In our research, RVFAC correlated with in hospital occurrence of MACE after adjustment for LVEF, but the study population consisted of post PCI patients with milder affected LV function (mean LVEF was 44.49+/-8.77%) than in the previous researches. RVEF represents a global measure of RV systolic performance and can be measured only with three-dimensional echocardiography, an expensive and not very available technique, yet. In our study, this is for the first time, by our knowledge, that RVEF assessed by three-dimensional echocardiography has

been demonstrated to correlate with in hospital MACE in AMI patients treated by primary PCI, after adjustment for LV function. (OR: 0.83 95% CI: 0.20- 3.43). The main limitations of this ongoing study are the small sample size and the length in evaluation. In future studies, we will evaluate larger sample of patients and if the RV functional echocardiographic parameters evaluated in acute state will have the same prognostic value on long term follow up as they had on short term follow up.

CONCLUSIONS

Our study reveals that RV functional parameters assessed by multiparametric echocardiography are predictive for in hospital MACE beyond LV systolic function and regardless of the localization of AMI or the culprit coronary artery. Among these parameters, RV MPI seems to have the greatest predictive value for short term all -cause mortality, reinfarction, need for revascularization or occurrence of heart failure in STEMI patients. This promising results requires validation in larger prospective studies. Consequently, more comprehensive echocardiographic evaluation including RV functional assessment should be implemented at hospital discharge in AMI patients for a better identification of patients at risk of adverse events. In addition, more precise characterization of RV function is warranted to improve our understanding of pathophysiological changes in RV physiology after reperfusion in acute STEMI patients.

ATYPICAL SPITZ TUMOR-CASE REPORT (Abstract): Atypical Spitzoid tumors represent a poorly defined and characterized category of melanocytic tumors with histologic features of both benign Spitz nevi and malignant melanomas. The group of atypical Spitz tumors represents a mixture of Spitz nevi with atypical features and Spitzoid melanomas. We report the case of an eight years old female patient, who was admitted in Dermatology Clinic Craiova for the presence of a skin tumor with 1/0.8 cm diameter, irregular edges, brown- black coloured with irregular pigment distribution. The skin tumor was located on the dorsal foot above the third metatarsal. The skin tumor appeared in the first two years of childhood and had a slowly increase. From about six months, the tumor had changed the colour becoming darker and had also a rapid increase in size. The patient had no comorbidities and had no family history of malignancy or other skin diseases. In our clinic we did the surgical excision of the skin tumor and sent the fragment for the histopathological examination and immunohistochemical tests. After the clinical examination, dermoscopic evaluation, histopathological and immunohistochemical examination, our diagnosis was Atypical Spitz Tumor. **Keywords:** ATYPICAL SPITZ TUMOR, SPITZ NEVUS, MELANOMA.

"Spitz nevus with atypia and metastasis" or "malignant Spitz nevus," was first described by Smith et al (1) in 1989 as a kind of lesion showing histopathologic features not enough for a diagnosis of malignancy, yet capable of nodal metastasis, usually with no further dissemination.

Barnhill then completes with the diagnostic category of "metastasizing Spitz tumor" (2), or "atypical Spitz nevus/tumor" (3).

Nowadays, some opinions are that there are only two diagnostic categories (nevus and melanoma) and that every "abnormal" behavior is simply a diagnostic mistake, and others suggest that Spitzoid lesions are indeed a "morpho-biologic spectrum" of lesions ranging from benignity to full-blown malignancy, and sharing a peculiar genetic profile, with chromosome rearrangements involving kinase fusions (4, 5, 6).

Intermediate lesions within such a spectrum have an equivocal histo-morphology, featuring a diagnostic agreement among

experts which is consistently lower than for "conventional" (non-Spitzoid) melanocytic neoplasms, but also peculiar clinical features and behavior with a relatively high incidence in prepubescent patients and a higher incidence of regional node involvement but a better prognosis than "conventional" melanoma of the same thickness/stage (possible low-grade malignancies) (7, 8, 9, 10).

CASE REPORT

We present the case of an 8-year-old female patient, who was admitted in Dermatology Clinic Craiova for the presence of a skin tumor with 1/0.8 cm diameter, irregular edges, brown-black colored with irregular pigment distribution. The skin tumor was located on the dorsal foot above the third metatarsal (fig. 1).

Fig. 1. Clinical aspect of the skin tumor

The skin tumor appeared in the first two years of childhood and had a slowly increase. From about six months, the tumor had changed, the color becoming darker and had also a rapid increase in size.

The patient had no comorbidities and had no family history of malignancy or other skin diseases.

After admission we performed dermoscopic examination which reveal nonspecific pattern with the presence of pigmented network, blue-white vale, white and black globules and white lines (fig. 2).

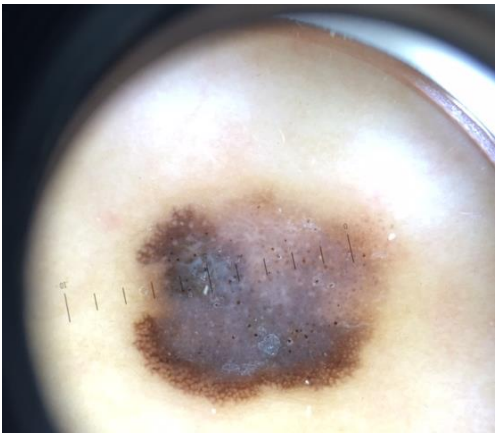

Fig. 2. Dermoscopic aspect of the skin tumor

In our clinic we did the surgical excision of the skin tumor and sent the fragment for the histopathological examination and immunohistochemical tests.

Histopathological examination revealed skin tumor with relatively symmetric architecture, histopathological aspect of proliferation of spindle cells, focal with intracytoplasmic accumulation of coarse melanin pigment arranged in large nests and isolated cells at the dermo-epidermal junction; numerous individual tumor cells and rare nesting with intraepidermic ascension and transepidermal elimination; extension in beams and isolated nests with minimum morphological maturation in the reticular dermis; tumoral cells have large nuclei, with 1-2 visible nucleoli, homogeneous eosinophilic cytoplasm; relatively frequent multinucleated tumor cells in surface; minimum interstitial fibrosis, rare mitosis in epidermal component; minimum lymphomonocyte inflammatory infiltrate with rare

melanofages peritumoral. The tumor proliferation has a tumor thickness of maximum 1.5 mm and extends laterally up to 2.5 mm from the closest lateral limit of fragments examined (fig. 3, 4).

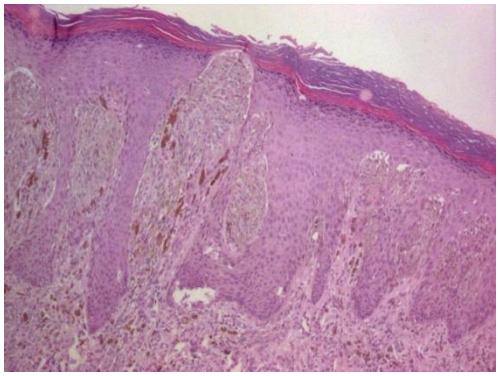

Fig. 3. Histopathological aspect of the skin tumor– HE col. X40

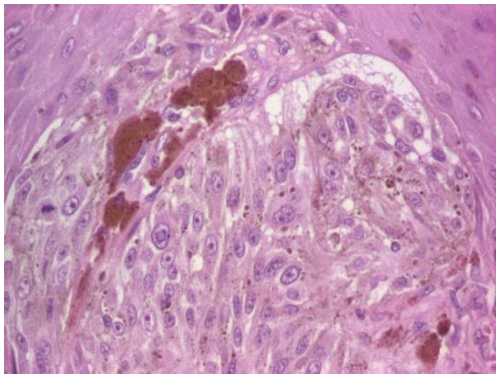

Fig. 4. Histopathological aspect of the skin tumor– HE col. X200

Immunohistochemical tests revealed HMB45- Positive tumor junctional component, positive in rare tumor cells in the dermis in the superficial part of the tumor (expression gradient compatible with the aging phenomenon); Tyrozinaza (T311)- positive junctional tumor component, positive in the dermis tumoral cells; p16- positive in the majority of tumor cells, small groups of tumor cells, predominantly those at intraepidermic level, negative; p21- positive in frequent nuclei of tumor cells; Cyclin D1- positive in tumor cells in both components (intraepidermic and dermal); Ki67- positive in about 1-2% of the tumor cells.

The test in fluorescence with co-location for Ki67 and protein S100 revealed two focuses were tumor cells shows relatively frequent nuclei Ki67-positive (index Ki67 4 positive nuclei/8 tumor cells and 3 Ki67 positive nuclei/7 tumor cells) without identified mitosis in dermal component. The test in fluorescence concluded histopathological and imunohistochimical aspects compatible with the diagnosis of Atypical Spitz Tumor.

After the clinical examination, dermoscopic evaluation, histopathological and immunohistochemical examination, our diagnosis was Atypical Spitz Tumor.

We indicated inguinal and popliteal lymph node ultrasound and the result was the absence of inguinal and popliteal lymph node metastases.

The patient was discharged with the indication of dermatological examination every 6 months.

DISCUSSION

Spitzoid tumors are estimated to be below 1% of melanocytic nevi in the first childhood but accurate data about incidence and prevalence are still not known. Atypical Spitz tumors (AST) associate minimal lethal potential, an increased melanoma risk, and a moderate risk of metastasis to regional nodes. Even today, there are no set of criteria to be used to predict the clinical outcome for atypical Spitz tumors with absolute assurance. AST occur more frequently in patients with Fitzpatrick Photo types I and II, affects both females and males and some authors describe a slight female predominance. About 50% of cases

occur in children under 10 years old and 70% of all cases are diagnosed in the first two decades of life (11).

From the clinical point of view atypical Spitz tumors present as a plaque or nodule, with variable size and localization. We can find a hypo pigmented reddish lesion or a brown-dark one. Regarding dermoscopic characteristics, nodularity, ulceration, linear vessels, polymorphic vessels, white lines, and blue-white veil are associated with atypical Spitz tumors (12).

The treatment recommended is surgical excision for all lesions with Spitzoid dermoscopic features detected after puberty. Before puberty, plaque-like or dome-shaped dermoscopic symmetric lesions with Spitzoid features can undergo dermoscopic digital monitoring (8). Large tumors over 1 cm, nodular or ulcerated tumors, rapidly growing or changing tumors, or otherwise atypical Spitz nevi of the childhood have to be surgical excised.

The management of patients with a histopathologic diagnosis of atypical Spitz nevus and Spitz tumor should be decided with a multidisciplinary approach. A re-excision can be considered for atypical Spitz nevi and has to be recommended for all incompletely excised lesions, as well as for Spitz tumors. The sentinel node biopsy for Spitz tumors should be evaluated case by case. A recent meta-analysis showed that 98–99% of young patients with Spitz tumors had no evidence of disease after a median follow-up of 59 months, regardless the sentinel node positivity. Therefore, the diagnostic and prognostic information given by a positive sentinel node in young patients seems to be negligible (10).

Echotomography of the regional nodes with an echotomography-guided fine needle aspiration biopsy cytology can replace sentinel node biopsy, because it allows to efficiently detect massive replacement of the lymph nodes by neoplasic cells, thereby addressing selected patients to election lymphadenectomy (13). This follow up protocol is probably the best choice in patients younger than 10 years, especially for lesions located in the head/neck area, a region in which surgical procedures have major aesthetically impact (14).

The management of the cases with atypical Spitz tumor depends also of patient age and the prognosis is also age-dependent (15, 16). Adult patients can be managed more aggressively.

The risk stratification for atypical Spitz melanocytic proliferations has been recently made with the use of a new four-probe fluorescence in-situ hybridization (FISH) assay for 6p25 (RREB1), 11q13 (CCND1), 9p21 (CDKN2a), and 8q24 (MYC). It resulted 4 categories: 1. Spitzoid melanoma with homozygous 9p21 deletion (high risk); 2. Spitzoid melanoma with 6p25 and/or11q13 gain (intermediate to high risk); 3. Atypical Spitz tumor with isolated 6q23 deletion (low risk); 4. Atypical Spitz tumor with no FISH abnormality (low to very low risk). But so far, the number of investigated cases is too low to validate this risk stratification system. However, the use of FISH techniques for prognostic purposes seems to be very promising (17).

Because of the lack of large studies of atypical Spitz tumor, no evidence-based treatment recommendations can be made.

Most current sources recommend complete excision to facilitate complete histologic evaluation and reduce risk of recurrence, but also they showed that very few sentinel lymph node biopsies are being performed for AST in clinical practice (18).

Atypical Spitzoid tumors represent a poorly defined and characterized category of melanocytic tumors with histologic fea-

tures of both benign Spitz nevi and malignant melanomas.

The group of AST represents a mixture of Spitz nevi with atypical features and Spitzoid melanomas (19).

CONCLUSIONS

This case report demonstrates that the diagnosis of pigmented tumors is difficult and it needs an experimental eye and performed investigations.

THE MOGE(S) CLASSIFICATION. A TNM-LIKE CLASSIFICATION FOR CARDIOMYOPATHIES

World Health Organization define cardiomyopathies as diseases of the myocardium associated with cardiac dysfunction. They were classified according to anatomy and physiology into the following types: dilated cardiomyopathy, restrictive cardiomyopathy (endocardial fibroelastosis), hypertrophic cardiomyopathy (athlete's heart), arrhythmogenic right ventricular cardiomyopathy, unclassified cardiomyopathies (left ventricular noncompaction, stress-induced cardiomyopathy, cirrhotic cardiomyopathy). Most cardiomyopathies are a familial disease and screening of the pedigree identifies asymptomatic family members for an early diagnosis cardiomyopathy. Genetic testing is increasingly becoming a part of the diagnostic process, and numerous new genes and mutations have been identified in the etiology of cardiomyopathies. Traditional definitions of cardiomyopathies, such as those by the American Heart Association and the European Society of Cardiology, do not consider the genetic basis of cardiomyopathies. In 2013, the World Heart Federation proposed a nosology that includes five simple attributes of a cardiomyopathy disorder: morphofunctional characteristic (M), organ involvement (O), genetic or familial inheritance pattern (G), an explicit etiological annotation (E) with details of genetic defects or underlying disease/cause, and information about the functional status (S) using the New York Heart Association (NYHA; I–IV) functional classes. The addition of (S) is optional, and should be used at the discretion. Using the description of the five attributes, the classification system has been designated as MOGE(S). The morphofunctional (M) notation provides a descriptive diagnosis of the phenotype: M_D = dilated cardiomyopathy; M_H = hypertrophic cardiomyopathy; M_A = arrhythmogenic right ventricular cardiomyopathy; M_R = restrictive cardiomyopathy; M_{LVNC} = LV noncompaction. Organ involvement (O) is defined as involvement of the heart only (O_H) or of other organs/systems. Healthy mutation carriers can be described as (O_0). The genetic/familial inheritance (G) notation gives information about autosomal dominant (G_{AD}), autosomal recessive (G_{AR}), X-linked (G_{XL}), X-linked recessive (G_{XLR}), X-linked dominant (G_{XLD}), or matrilineal (G_M) transmission. The etiological notation (E) adds to the information on the underlying cause. The MOGE(S) system resembles the TNM classification system for malignancy, and therefore it can be useful for the diagnosis, management, and treatment of cardiomyopathies in a similar manner to cancer management (E. Şahan, S. Şahan, M. Karamanlioğlu, M. Gul, O. Tufekcioğlu. The MOGE(S) classification. A TNM-like classification for cardiomyopathies. *Herz* 2016; 41(6): 503–506).

THE "DARK SIDE" OF DEEP VEIN THROMBOSIS - CASE REPORT (Abstract): Venous thromboembolism (VTE) is an increasingly common cause of morbidity and mortality in cancer patients. In various malignancies the incidence of thrombosis ranges from 5% to 60%, that is four times higher in cancer patients compared to the general population. Large retrospective studies have shown that in men the tumors which are most commonly associated with VTE are lung cancer and pancreatic cancer and, in women cancer of the genital area, pancreas, colon and rectum. Thromboembolic events may often occur before the cancer diagnosis. We present the case of a 41year-old female patient with a history of genital cancer which was surgically treated and who is now admitted for clinical signs of ileofemoral deep vein thrombosis (DVT) of the left leg. The diagnosis was confirmed by laboratory data and Doppler ultrasound and the patient received anticoagulant treatment. Given the history of the patient, abdominal and pelvic ultrasound and computer tomography (CT) were performed to detect the cause who predisposed to the thrombotic event. These confirmed the ovarian cancer, this time on the right side, and the presence of hepatic and pulmonary metastasis. This case highlights the importance of screening for a cause of the thromboembolic event in patients, especially in those who have a history of a neoplasia. **Keywords:** DEEP VEIN THROMBOSIS, MALIGNANCY, PARANEOPLASTIC SYNDROMES.

The association between malignancy and clinically manifest thrombosis in various sites has been recognized for almost 140 years. It was first described by Armand Trousseau in 1865 who noted that "in cancer patients a special condition of the blood predisposes to spontaneous coagulation" (1, 2). Hypercoagulable state is a characteristic of cancer patients and the spectrum of hemostatic disorders extends from abnormal coagulation tests in the absence of clinical signs, to massive thromboembolism at various sites (2 - 4). Thrombotic episodes may precede malignancy by months or days and can manifest in various forms: superficial migratory thrombophlebitis (Trousseau syndrome), nonbacterial thrombotic endocarditis, disseminated intravascular coagulation – DIC (malignancy is considered the third cause of DIC after infection and trauma), thrombotic microangiopathy. Arterial thrombosis can also occur (but less frequently than vein thrombosis), and is due to nonbacterial thrombotic endocarditis (2). The incidence of thrombosis ranges from 5% to 60% in vari-

ous malignancies, which is four times higher in cancer patients compared to the general population (3). In men, pancreatic and lung cancer are most commonly associated with VTE and in women - the genital area, pancreatic and colorectal cancer (5). It is worth remembering that not infrequently vein thrombosis may precede by a variable period of time the occurrence of the specific clinical picture of cancer (2).

CASE REPORT

We present the case of 41-year-old woman who was admitted to the Department of Cardiology, „Sf. Spiridon" Emergency Clinical Hospital Iaşi, for edema and pain in the left leg, occurring relatively quickly, in the last 48 hours, suggestive for the clinical diagnosis of iliofemoral thrombosis of the left leg.

The past medical history revealed that at the age of 37 years she underwent left oophorectomy and subtotal hysterectomy for ovarian tumor, the anatomopathological diagnosis findings being low-grade malignant stromal sarcoma, for which chemotherapy was not indicated but periodic checkups were recommended. The current diagnosis of deep vein thrombosis was confirmed by the presence of elevated raised D-dimers and Doppler ultrasound of the lower legs which showed incomplete thrombosis of the left external iliac, left common femoral and left popliteal veins (fig. 1).

Fig. 1. Doppler ultrasound of lower limbs showing thrombosis of the left common femoral vein

Laboratory data revealed: a mild inflammatory syndrome (ESR: 57 mm/h, fibrinogen: 5.65 g%), normal white blood cell and platelet counts, absence of anemia, negative result in antiphospholipid antibody test (the latter excluding a possible thrombophilia). The remaining laboratory data were within normal range.

Unfractionated heparin therapy via syringe pump monitored with activated partial thromboplastin time (APTT) was initiated, and laboratory tests were performed to elucidate the cause of DVT (fig. 2).

Given the history of genital cancer, abdominal and pelvic ultrasound scan was performed, which showed a cystic mass on the right ovary associated with liver metastases. Chest X-ray demonstrated pulmonary metastases, all these changes being confirmed by thoracoabdominal CT which in

its turn confirmed that the right ovarian cystic mass detected by ultrasound was in fact a right ovarian cystic neoplasm with liver and pulmonary metastases.

The final diagnosis was: paraneoplastic left iliofemoral vein thrombosis, right ovarian cystic cancer, liver and lung metastases.

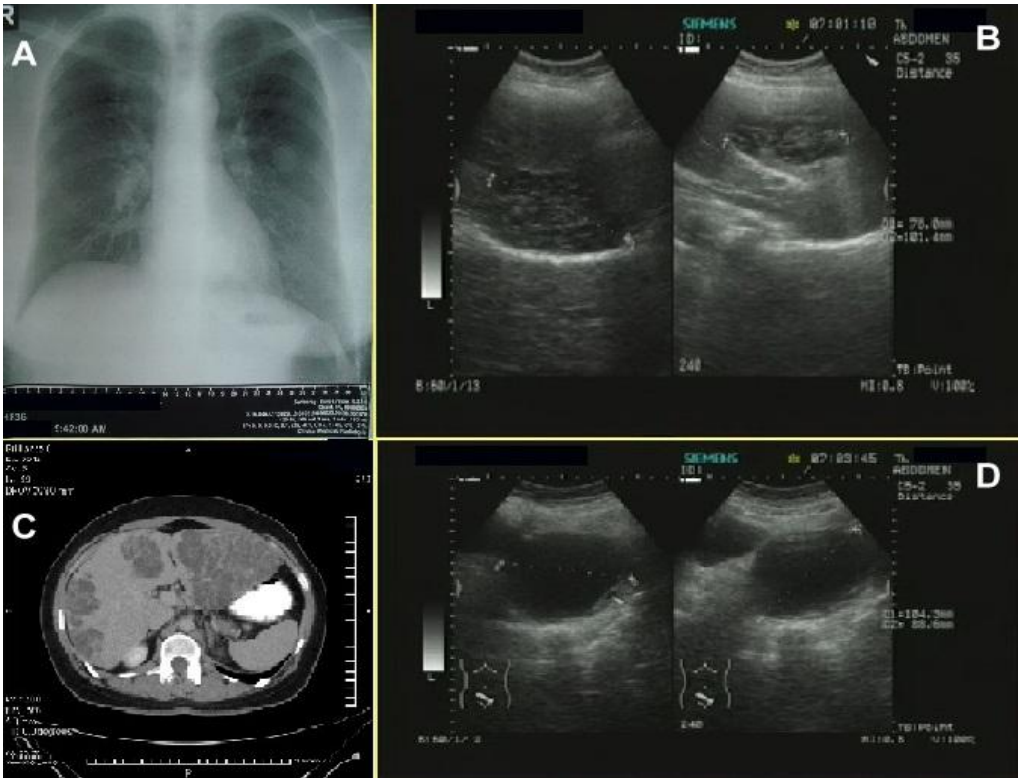

Fig. 2. A: Chest X-Ray showing left pulmonary metastases; B: Abdominal ultrasound showing liver metastases; C: Abdominal CT showing liver metastases; D: Pelvis ultrasound scan showing ovarian cysts with signs of malignancy

DISCUSSION

The occurrence of a prothrombotic status in cancer patients depends on the type, location and extent of the tumor, response of the host organism, as well as on therapeutic regimens used (2, 6, 7). The main mechanisms involved in the induction of prothrombotic states are:

- excessive thrombin production by an extrinsic pathway due to secretion by certain tumors of tissue-like factors (e.g.: gastric and pancreatic tumors) (2, 8, 9); these tumors frequently cause recurrent and migratory venous thrombosis (Trousseau) (2);

- production of thrombin directly by intact tumor cells that may express procoagulant activity; sometimes normal host tissues can express procoagulant activity in response to the tumor.

Malignant tumors can secrete substances with procoagulant activity mainly of two

types: tissue factor and cancer procoagulant. Tissue factor forms a complex with activated factor VII and factor IX and X leading to the initiation of coagulation and cancer procoagulant is a calcium-dependent cysteine protease which directly activates factor X, independent of tissue factor and activated factor VII (2). Monocytes, which normally do not have procoagulant activity can be stimulated, under certain conditions, to produce tissue factor or other direct activators of factor X by T lymphocytes, antigens, cytokines, lipoproteins, immune complexes, endotoxins (2). Also, the presence of a malignancy in the body produces an abnormal platelet activation which aggravates the hypercoagulable state. The endothelial cells may become procoagulant under the influence of pro-inflammatory cytokines or other peptides, and in particular due to TNF and IL-1 which increase the expression of leukocyte adhesion molecules, platelet activating factor and tissue factor. TNF also reduces the fibrinolytic activity of endothelial cells, increases endothelial production of IL-1 and expression of thrombomodulin which decreases the anticoagulant protein C activation (2, 8 - 10). Additional risk factors for VTE in patients with malignancies include: age, race, comorbidities, history of VTE, cancer site, metastases, recent surgeries, chemotherapy, central venous catheters and sepsis (2, 8 - 11). The period of 3-6 months after diagnosis is characterized by an increased incidence of VTE. Another mechanism by which malignant tumors can cause venous thrombosis, besides inducing hypercoagulable state, is extrinsic compression or direct vascular invasion (2, 11).

The literature review showed that different reported cases of VTE episodes were in the end diagnosed with occult malignancy (12 - 19). Each of them has its particularities: atypical location of venous thrombosis, bilateral involvement, or different types of cancer. As to the tumor markers, which were negative in our patient, cases reported in the literature presented either positive or negative tumor markers, depending on the histopathological type (13, 14, 20).

CONCLUSIONS

There are some particularities of this case: 1) Discovery of a cancer relapse in metastatic stage in the guise of DVT; 2) Paraneoplastic DVT usually occurs in adenocarcinomas (in our case the first tumor was low-grade malignant stromal sarcoma); 3) Absence of tumor markers even in the presence of metastases.

We believe that clinical history taking, routine laboratory findings, together with chest X-Ray and abdominal ultrasound are valuable screening tools for occult malignancy, especially in cases with atypical form or apparently idiopathic VTE.

SHORT TERM EVALUATION ON VISUAL DECLINE IN PATIENTS WITH OPEN ANGLE GLAUCOMA AND DIABETES (Abstract). **Aim of study:** progression rate in patients with glaucoma and diabetes. **Material and method:** cohort prospective study in Ophthalmology Clinic - "Sf. Spiridon" University Hospital – Iaş i. We recruited patients with positive history for diabetes and of open angle glaucoma (OAG). The control group included subjects with OAG (74 eyes from 74 patients) and the study group (44 eyes, from 44 patients) included subjects with OAG and diabetes. At enrollment all patients had a complete ophthalmologic evaluation along with full metabolic status assessment. There were included only incipient and moderate forms of glaucoma, with mild or no diabetic retinopathy changes. Perimetric progression was assessed at 24 months with automated methods. **Results**: globally, from 118 investigated eyes, 56.40% cases had primary open angle glaucoma, 41.03% normal tension glaucoma and 2.36% pseudoexfoliative glaucoma. Glaucoma severity classification showed early defects (mean deviation < -6 db) in the study group of 77.27% vs.83.78% in control group, whereas moderate defects (mean deviation > -6 db) were found in 22.63% in study group vs 16.21.0% in control group. Mean age of the patients was higher in absolute value in the open angle glaucoma group (64.31 +/- 1.66 years), vs diabetes + open angle glaucoma (62.69 +/- 1.8 years), with comparable visual acuities (0.91 +/-0.15 vs 0.89 +/-0.16), C/D ratios and other clinical parameters (p>0.05). Mean baseline IOP in the study group was 18.18 +/- 3.55 mmHg vs.17.08 +/-2.4 mmHg in controls (p>0.05). Analysis of visual field parameters at baseline showed a significant difference (p=0.0.48) between groups in MD levels -3.63 +/- 3.35 db (control group) vs -4.40 +/- 5.78 db (study group), but no difference (p>0.05) in PSD levels: 3.71 +/- 3.06 db (control group) vs 4.05 +/- 3.04 dB (study group). Perimetric progression was estimated at 24 months by Glaucoma Progression Analysis software (GPA –Humphrey Visual Field Analyzer II) using 6 reliable visual field (VF) exams. Progression rate was similar between groups - 0,19 ± 0,78 dB/year (OAG) vs. – 0.18 ± 0,05 dB/year (OAG+DM), p>0.05 and no other risk factor could have been linked to an increased progression rate, except visual field parameters at final and baseline evaluation, in both groups. **Conclusions:** on short term, functional deterioration in open angle glaucoma patients having early or moderate stages, occurs similarly in the presence or absence of diabetes. **Keywords**: SHORT TERM, PERIMETRIC PROGRESSION, OPEN ANGLE GLAUCOMA, DIABETES.

Glaucoma represents an optic neuropathy that can lead to optic nerve irrevesible damage and blindness. Among all glaucoma types, primary open angle glaucoma is

the most common form and a leading cause of visual loss wordwide (1).

Individual evolution is highly variable, despite adequate treatment (2,3). In consequence, visual field changes and progression rates differ greatly (4,5).

Recent literature data mention the contribution of risk factors in glaucoma progression such as older age, decreased corneal thickness, pseudoexfoliation, low ocular perfusion pressure, disk hemorhages, baseline visual field parameters or systemic diseases like diabetes, hypertension and cardiovascular events (3,6). Thus, the aim of our study was to assess if progression rate in patients with open angle glaucoma and diabetes is different on short term evaluation (24 months).

MATHERIAL AND METHOD

Our study was designed as cohort prospective clinical trial and included a total of 118 eyes from 118 patients (73% males, 27% females), recruited in the Ophthalmology Clinic - "Sf. Spiridon" University Hospital – Iaş i, between October 2012-March 2014. The patients were divided in two groups as following: 44 eyes, from 44 patients in the study group (diabetes + open angle glaucoma) and the control group with 74 eyes from 74 patients with open angle glaucoma (primary open angle glaucoma, normal tension glaucoma and pseudoexfoliative glaucoma). At enrollment all patients had a complete ophthalmologic evaluation and metabolic status assessment. We included only incipient and moderate forms of glaucoma, with mild or no diabetic retinopathy changes.

The diagnosis of glaucoma was defined in the presence of open anterior chamber angle on goniscopy, glaucomatous optic disc damage on clinical examination (focal or diffuse neuroretinal rim thinning, localized notching, or nerve fiber layer defect) and corresponding visual field (VF) defects. Glaucoma severity was graded according to Hodapp criteria (7). Diabetes was confirmed by previous tests in our patients in the Diabetology Department. We selected only those cases with no/mild form of diabetic retinopathy.

At baseline we recorded clinical parameters that included: age, gender, best corrected visual acuity (BCVA) by ETDRS chart, intraocular pressure (IOP) by Goldmann tonometer, CCT by ultrasonic pachymetrer (DGH-550, DGH Technology Inc., Exton, PA, USA) CD ratio (Volk 78D lens), number of topical medications, VF test parameters; at each follow up visit VA, IOP and VF tests were repeated. During the study the patients were followed each 3 months, when identical tests were performed. The last visit evaluated visual acuity, IOP, VF parameters. Majority of patients required topical therapy with 1-2-3 standard antiglaucoma medications. During monitoring, treatment was modified if the IOP was not efficiently controlled. Intermediary IOP was calculated by averaging all the IOPs taken during the 24 months follow up interval.

Exclusion criteria were related to significant lens opacities, other ophthalmic comorbidities, refractive errors >5D spherical, >3D cylinder. If both eyes were eligible, only one was chosed based on the worse mean deviation (MD) level at baseline

In Standard Achromatic Perimetry (24-2 SITA Standard SAP, Humphrey Field Analyzer II, Carl Zeiss Meditec Inc., Dublin, CA, USA) VF changes for glaucoma were defined if at least two of the three Anderson's criteria were fulfilled (three or more non-edged points in a cluster depressed to $P<5\%$ and one of which depressed to

P<1%, Glaucoma Hemifield Test outside normal limits and pattern standard deviation depressed to *P*<5%). Tests with fixation losses, false-positive or false-negative rates >20% were excluded from the analysis. 6 reliable visual fields were analyzed from each patient and the first two tests served as baseline landmark; progression was evaluated by Glaucoma Progression Analysis software. The event-based progression analysis, Glaucoma Progression Analysis (GPA) software used statistical criteria designed for the Early Manifest Glaucoma Trial to identify progression of VF defects (10). When significant (*P*<0.05) deterioration was evident on the pattern standard deviation (PSD) maps at the same three or more points on two consecutive follow-up tests, the GPA alarmed for 'possible progression'; if significant deterioration was seen at the same three or more points in three consecutive follow-up tests, GPA alarmed for 'likely progression'. When both the above criteria were not met, the software flagged as 'no progression detected'. For the purpose of this study, progression was quantitatively assessed by liniar regression analysis of the mean deviation (MD) changes over time; slopes of progression (decibels/ year) based on threshold maps and its level of significance (p-values) were calculated.

During the study the patients were followed each 3 months, when identical baseline tests were performed.

A SPSS 18.0 statistical software (SPSS Inc. Chicago, IL, USA) was used to process the data. Descriptive analysis was used on demographics, follow up time MD, PSD and IOP. Progression rate (MD slope) was calculated by linear regression analysis of MD values over time and expressed in dB/ year. Independent samples t tests were used for comparisons of continuous variables between groups. Also when paired groups were compared (baseline and final parameters) we used Wilcoxon test. Spearman's correlation coefficients (r) were calculated to assess the relationship between age, BCVA, MD, PSD, IOP and MD slope. Statistical significance was defined at the p <0.05 level.

RESULTS

From all the 118 eyes included in our study, 58.96% cases had primary open angle glaucoma (POAG), 41.03% cases had normal tension glaucoma (NTG) and 2.56% cases with pseudoexfoliative glaucoma (PXG), as shown in fig. 1. Sex ratio (F:M) was 1:2.9 (study group) and 1:1.5 (control group).

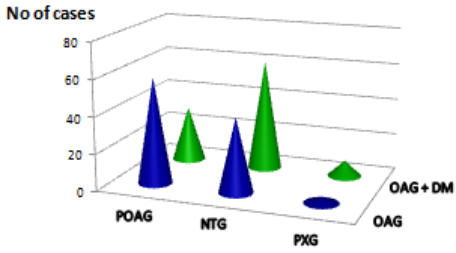

Fig. 1. Glaucoma type distribution in the two groups

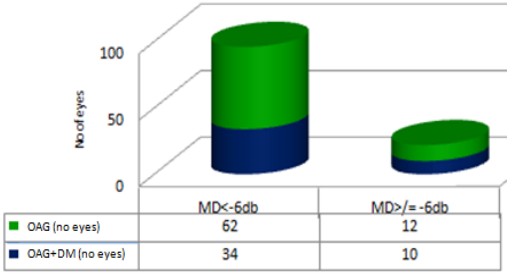

Fig. 2. Glaucoma severity classification (Hodapp criteria) in the 2 groups

Glaucoma severity classification showed early defects (MD < -6 db) in the study group of 77.27% vs. 83.78% in control group, whereas moderate defects (MD > -6 db) were found in 22.63% in the study group versus 16.21% in the control group, shown in fig. 2.

Baseline parameters and their evolution compared between the two groups were synthesized in table 1. The only statistically significant difference we found was related to the MD level at start, as the eyes with diabetes and OAG were more depressed in retinal sensitivity compared to the cases that had only OAG. All the other parameters were comparable and with no significant differences, meaning that we could compare homogenous groups, although the number of cases was not equal between them.

TABLE I

Parameters compared between groups at initial visit and during follow up

Baseline parameter	OAG+DM	OAG	T Student Test
Eyes (no)	44	74	nss
Age	62.69+/-1.8	64.31+/-1.66	nss-
Sex ratio (F:M)	1 : 2.9	1 : 1.5	nss
BCVA-ETRDS	0.91+/-0.15	0.89+/-0.16	nss
Sph. Eq	0.34+/-0.24	0.32+/-0.19	nss
CCT (μm)	538±35.9	528±62.8	nss
IOP (mmHg)	18.18±3.55	17.08±2.4	nss
MD (dB)	-4.40 ±5.78	-3.63+/3.35	p=0.02
PSD (dB)	4.05±3.04	3.71±3.06	nss
No. of medications	1.43±0.90	1.62+/-1.13	nss
Follow up parameters			
VF exams	6	6	-
BCVA-ETRDS	0.85±0.21	0.83±0.21	nss
IOP (mmHg)	16.49±2.81	16.62±2.90	nss
MD (dB)	-5.64±6.89	-5.3±6.25	nss
PSD (dB)	4.38±3.49	4.22±3.49	nss
MD slope (dB/ year)	-0.19 ± 0.78	-0.18± 0.05	nss

nss – not statistically significant

In evolution at 24 months we observed in the study group (OAG and diabetes) a statistically significant change in IOP level (18.18+/-3.55 mmHg vs. 16.49+/-2.81 mmHg, p=0.03) and in mean MD level (-4.40 ±5.78 vs. -5.64±6.89, p=0.04), aspect

shown in fig. 3,4.

Rate of glaucoma progression (MD slope) at 24 months was similar and did not differ statistically, but only in absolute value: -0.19 dB/year (OAG+DM) versus -0.18 dB/year (OAG), p=0.55 (t test).

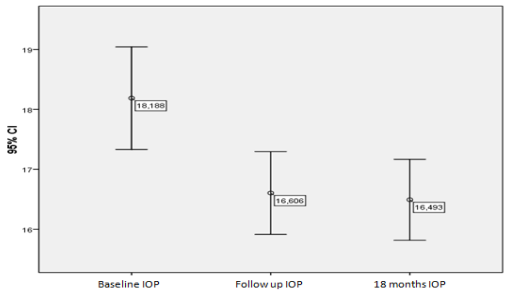

Fig. 3. IOP variation in the study group (OAG+DM): initial vs. follow up vs. final visit (24 months)

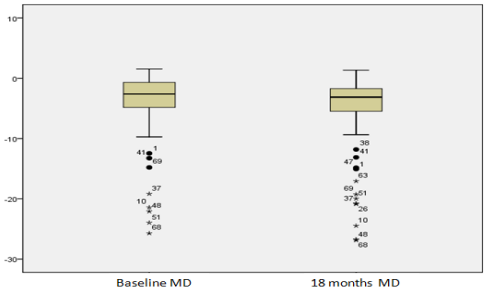

Fig. 4. MD mean values – baseline vs. 24 months in the study group (OAG+DM)

A more significant decrease in IOP level in the study group between baseline and after 24 months of follow up could be interpreted in the context of a more aggressive treatment applied initially to the patients with combined disease (OAG+DM) based on a hypothesis that all eyes are more prone to a more significant visual decay than the control group.

Spearman's coefficient detected significant correlations in the study group between MD slope and final/ initial MD levels (p=0.000), but also with baseline IOP (p=0.032). Intermediary IOP was correlated with final PSD (p=0.04), baseline IOP (p=0.000) and baseline MD (p=0.016). Both final and baseline visual field parameters were highly correlated, as expected at a p=0.000. Interestingly, MD slope in the study group was correlated (p=0.043) with the number of topical medications, but when age was controlled, the correlation became not significant any more.

In the control group we found the same type of correlations between MD slope and visual field parameters. Thus MD slope was correlated both with these parameters at baseline MD (p=0.039) PSD (p=0.011) and final MD level (p=0.011).

DISCUSSIONS

Progression rate and risk factors are among the most important aspects in glaucoma care because of their impact upon visual decay (8, 9, 10).

We found that visual field progression rate (MD slope) in both groups was dependent and correlated to both baseline VF parameters (MD/PSD) and also the final MD level ($p<0.05$). In this aspect, our results were similar to the OHTS (11) or EMGT study (12), where the initial MD level predicted progression rate in hypertensive glaucoma forms. Additionally in EMGT results, by reducing the IOP with 25%, progression occured later than in non-treated patients. This could also be the reason for our patients progressing at such a low rate compared to other studies, since medication was constantly changed/ added

to lower the IOP aiming for "the lower, the better" concept. No differences were detected in progression rate between patients with open angle glaucoma and diabetes compared to non-diabetic patients on short term evaluation. MD slope was similar in absolute values and no statistical significance could be attributed, p=0.55 (t test). Calculated MD slope at 24 months was -0.19 dB/year in OAG+DM group compared to -0.18 dB/year in OAG group.

In the study group we found correlations between MD slope and mean IOP at baseline; also there was a correlation between visual field decay and the number of topical medication, but when age was controlled the correlation was not significant anymore. Clinically this was associated with a more aggressive treatment from the beginning, in order to prevent a more rapid progression, as previously described by recent literature data where diabetes triggered faster glaucoma progression.

Preliminary analysis of progression at 24 months represented an important step in monitoring correctly both OAG patients and OAG+diabetes patients, as around this interval we could rule out fast progressing cases (MD slope >-2dB/year). Limitations of our study were basically the small number of patients and the short term evaluation of glaucoma progression, as all major clinical trials reported data after 4 years minimum (3,5); a clear image of glaucoma progression could have been obtained after a longer period of follow up, as it is known that in the first two years the investigators could only obtain a rough estimate. Still the reason for this evaluation was to rule out fast progressors (MD slope decay >-2dB/year).

CONCLUSIONS

In conclusion on short term evaluation (24 months), the visual field loss and functional deterioration in open angle glaucoma patients having early/ moderate stages, occurs similarly in the presence or absence of diabetes and no fast progressor was detected in our study during this interval.

NEWS

THE INCIDENCE OF INVASIVE MRSA INFECTIONS IN GERMANY MAY BE DECLINING

As ECDC mentioned in the Annual epidemiological report for Antimicrobial resistance and healthcare-associated infections 2014 (data for 2012), while MRSA remains a public health priority as the percentage of MRSA isolates is still above 25% in seven of 29 reporting countries, mainly in Southern and Eastern Europe, including Romania (>50%), a recently published study showed that the incidence of invasive MRSA infections in Germany may be declining. MRSA infections in Germany are thought to be mainly healthcare-associated with only a small proportion, which are community-associated or livestock-associated. The notification of MRSA infections is mandatory in Germany since 2009 for microbiological laboratories. A team of researchers conducted a retrospective cohort study in the general population of Germany. The analysis was limited to the period from 2010 to 2014. Data of notifications of invasive MRSA infections for the above-mentioned period were extracted from the national surveillance database at the Robert Koch Institute as collected up to 1 March 2015 (Walter J, Haller S, Blank H et al.Incidence of invasive meticillin-resistant Staphylococcus aureus infections in Germany, 2010 to 2014. *EuroSurveill*. 2015; 20(46):pii=30067. PSYCHOTIC DISORDERS GENERATED BY AUTOIMMUNE ENCEPHALITIS (CLINICAL CASE) (Abstract): Encephalitis is a brain inflammation, which could involve also the meninges. The etiology of encephalitis could be: viral, bacterial, fungal or autoimmune. Anti-NMDAR encephalitis is an immune disorder, easy to diagnose and is a treatable condition. Most patients with anti-NMDAR encephalitis develop a multistage illness that progresses from psychosis, memory deficits, seizures, to catatonic state and breathing instability. We present a case report of a 20-year old woman, who presented: amnesia, visual hallucination, illusions, seizures after that occurred following autoimmune encephalitis. The exact incidence of anti-NMDAR encephalitis is unknown, but it seems to be more frequent than any other known paraneoplastic encephalitis. The present case is important considering that autoimmune encephalitis is a rare frequency disorder in Romania, with patients presenting resounding psychiatric and neurological manifestations. **Keywords:** AUTOIMUNE ENCEPHALITIS, PSYCHOSIS, NMDA ANTI-RECEPTORS.

Infectious psychoses represents specific psychiatric manifestations that may appear during infectious diseases. The occurrence of psychic disorders is related to the type of infectious agent, the patient's constitution and the biological and psychological status of the affected organism. The infectious agent could be: a virus, bacteria, rickets, protozoa etc (1, 2). Since its discovery in 2007, the encephalitis associated with antibodies against the N-methyl-D-aspartate receptor (NMDAR) has entered the mainstream of neurology and other disciplines. The exact incidence of anti-NMDAR encephalitis is unknown (3).

In 2005, studies described a syndrome manifested by: memory deficits, impairment in consciousness and other psychiatric manifestations in young women diagnosed with ovary teratoma. In these patients specific anti-NMDA antibodies were detected. Two years later, in 2007, this syndrome was called anti-NMDA antibodies encephalitis.

The disorder occurs with or without tumor association, and responds to treatment but can relapse. The presence of a tumor (usually an ovarian teratoma) is dependent

on age, sex, and ethnicity. The disorder predominantly affects children and young adults. About 80% of patients with anti-NMDAR encephalitis are women (3, 4, 5). About 70% of patients have prodromal symptoms consisting of fever, nausea, vomiting, or upper respiratory-tract symptoms. Within a few days, usually less than 2 weeks, patients develop psychiatric symptoms (visual hallucination, illusions) and many are seen initially by psychiatrists. Patients respond well to immunotherapy, but psychiatric symptoms can be challenging to manage. Anxiety, insomnia, fear, grandiose delusions, hyper-religiosity, mania, and paranoia are frequent manifestations (3,6,7). After diagnosis, treatment focuses on immunotherapy and appropriate treatment of a tumor if it exists. Corticosteroids and intravenous immunoglobulin (Ig) or plasma exchange are recommended in managing the immune response (4).

In this case report we present a young woman that suffered an aggressive autoimmune encephalitis witch presents resounding psychiatric and neurological manifestations.

CASE REPORT

A 20-year-old woman, with no recorded medical history, presented in March 2015 with several medical complains, such as: headache, vertigo, tremor of the arms and balance deficits at the Infectious Diseases Hospital. Initially, the patient is hospitalized at the Infectious Diseases Hospital for 4 weeks. Further one, the patient was transferred to „Prof. Dr. Nicolae Oblu" Clinical Neurologic Hospital, for 2 weeks. During hospitalization at the Infectious Diseases Clinic (4 weeks) and at the Neurology Clinic (2 weeks), interdisciplinary examinations were made at the "Socola" Psychiatry Institute.

At this stage of the disease, the imagistic evaluation such as tomography, cranial-cerebral MRI (nuclear magnetic resonance imaging), MRI angiography, CIV were normal.

The disease progresses with new symptoms and aggravation of the older one with rapidly progressive confusion syndrome, psychiatric phenomena, tremor and bilateral extra-pyramidal rigidness. The psychiatric status is progressively altered with hallucinatory episodes, psycho-motor agitation, and disturbances of orientation and memory.

The neurological examination raises the suspicion of anti R NMDA autoimmune encephalitis and the patient is transferred at the Neurology Clinic for treatment. The examination revealed: confusion state, diminishing attention, speech and memory deficits, seizures, amnesia. Mini-Mental State Examination (MMSE) was initially 15 points. Also, during her hospital stay at the Neurology Clinic, the patient benefited from psychological consults, in witch an increase of MMSE from 15 points to 18 points was observed. The patient was examined by a gynecologist and neither ovary teratoma, nor other forms of tumors were found.

Further one, the patient developed generalized tonic seizures, and oral and tracheal intubations were performed and ICU (Intensive Care Unit) stabilization was mandatory for 41 hours.

Our patient, cerebrospinal fluid (CSF) was examined and the results indicated anti-NMDAR encephalitis. Patient electroencephalograms (EEG) presented increased incidence of theta rhythm on bilateral hemispheres with rare sharp, asynchronous left TPO (temporal-parietal-occipital) waves.

Without any psychiatric history, the pa-

tient presented into the ambulatory of the "Socola" Psychiatry Institute in March 2015, with confusion, visual hallucinations, unsteady gait and extra-pyramidal syndrome. At her second psychiatric exam, in April 2015 the patient was confused, partially oriented to space and time, and presented generalized tremor of the extremities. A month later, in May 2015, the patient had the next psychiatric consultation in ambulatory setting. Following the psychological exam a MMSE (Mini Mental State Examination) of 23 points is noted. The patient is treated with a combination of antipsychotic and benzodiazepines.

During Infectious Diseases Clinic and Neurological Clinic hospitalization, the patient received treatment with corticosteroids, cerebral anti-edematous medication, liver-protective medication, hydro-electrolytic support. The evolution is slowly favorable under a high dosage corticoid treatment.

DISCUSSION

We also discuss several confounding factors that often delay the recognition of this disorder, and propose an algorithmic strategy to guide treatment. Many symptoms that a patient presents (bizarre or stereotypical behaviors, insomnia, and memory deficits) cannot be classified as cortical (3).

The current knowledge about autoimmune encephalitis is that the disorder evolves progressively, with psychotic symptoms, convulsions, memory impairment, and speech disturbances up to a comatose state. In majority of cases, this disorder could be associated with tumors, such as ovary teratoma in approximately 90% of the total cases. In only 2% of the cases may include other types of tumors such as: Hodgkin's lymphoma, or mammary tumors. At our patient, neither ovary teratoma, nor other forms of tumors were found. The autoimmune encephalitis responds well to adequate treatment, but the risk of future relapses is also present (1, 5). About 70% of patients have prodomal symptoms consisting of headache, fever, nausea, vomiting, diarrhea, or upper respiratory-tract symptoms. Within a few days, usually less than 2 weeks, patients develop psychiatric symptoms and many are treated initially by psychiatrists. Short-term memory loss is common but underestimated (3).

Electroencephalograms (EEG) are abnormal in most patients, usually showing disorganized activity, sometimes with electrographic seizures. Slow, continuous, rhythmic activity in the delta-theta range predominates in the catatonic stage (3). Electroencephalograms (EEG) are abnormal at our patient, with predominant theta waves. The cerebrospinal fluid (CSF) is initially normal in 80% of patients and becomes abnormal later. At our patient, the results indicated anti-NMDAR encephalitis.

In our case we did not find teratomas, but the clinical evolution with: seizures, impaired memory, speech and comatose state and the laboratory exams sustain the diagnostic mentioned above. Almost 75% of the patients with severe anti-NMDAR encephalitis are fully recovered or remain with mild sequels (2, 3, 7). The present case received high-dose immunosuppressive therapy, anticonvulsants and antipsychotic to reduce symptoms. The patient remains under close medical supervision with mild sequels (amnesia) (4, 5, 6).

In patients without a tumor (in whom relapse is more common), continued im-

munosuppressive therapy is recommended for at least 1 year and periodic screening for an ovarian teratoma over 2 years (4).

CONCLUSIONS

In the present clinical case, the patient diagnosed with autoimmune encephalitis remains with mild symptoms such as a persistence of amnesia 2 months after the illness occurred. Also, high risk of relapse is considered in case of this patient.

This complex disorder requires sustained management and coordination of care between multiple medical specialties. Future clinical work will need to examine, in depth, the psychiatric manifestations of the disorder and how to provide optimal care, not only during acute faze hospitalization but also in the prolonged recovery process. Future studies should clarify the best treatment approach, and clinical strategies to accelerate the process of recovery.

VALUE OF DOPPLER ULTRASOUND IN DECISION MAKING FOR CESAREAN SECTION

VALUE OF DOPPLER ULTRASOUND IN DECISION MAKING FOR CESAREAN SECTION DECISION (Abstract). Based on the Doppler phenomenon, several tools were developed that are able to measure the blood flows in various vessels. The authors aimed at determining whether in some cases such an examination is sufficient to decide if a cesarean section is indicated. According to the literature and authors' own professional experience, the answer to this question is yes, as the most advanced method measures diastolic flows in the umbilical artery. Fetuses with intrauterine growth restriction are the most suited for this assessment. In less clear-cut cases, doctors may resort to middle cerebral artery, ductus venosus, uterine artery and umbilical vein assessments, or to biophysical score calculations. Any obstetrical approach should consider the fetal gestational age, condition and weight, and the corroborated results of the various flow and velocimetry measurements. The authors suggest a continuation of this research, the ultimate goal being the development of an overall score including several types of Doppler examinations, which would improve assessment accuracy. **Keywords**: DOPPLER ULTRASOUND, CESAREAN SECTION, INTRAUTERINE GROWTH RESTRICTION, FETAL MONITORING.

Doppler ultrasound scanning of fetal circulation has already become a current method for the assessment of prebirth fetal condition. Our paper aims to determine whether in some cases such an examination is sufficient to decide whether a cesarean section is indicated. The answer to this question is yes, and intrauterine growth restriction (IUGR) is the best application for this method.

History. Christian Andreas Doppler (1803-1853), an Austrian mathematician and physicist, discovered the wavelength alteration phenomenon depending on the relative speed between the source and the receptor. The piezoelectric effect was discovered by Pierre and Jacques Curie, in 1880.

The Doppler Effect started to be used for medical purposes towards the end of the 1950's. The pulsatile Doppler dates back to 1966 (1).

Umbilical artery (UA) velocimetry. Vasoconstriction of the tertiary villi is considered responsible for the velocimetric alterations in the umbilical artery blood flow, consisting in a decrease in diastolic velocities and an increase in the resistance and impedance indices. Evidence of any histological placental alterations due to

absent or reversed diastolic flow is still lacking. Currently it is believed that reversed blood flow is the last stage of the spectrum of placental insufficiency, with a high risk of perinatal death. It seems that over 50% of the placental vessels have to be obstructed before absent or reversed diastolic flow in the umbilical artery to occur in (2).

Studies in which IUGR fetuses were longitudinally monitored showed that up to 80% of them had abnormal umbilical indices two weeks before the fetal acute deterioration. End-diastolic velocities are present approximately one week before acute deterioration. Up to 40% of the fetuses with acidosis have this abnormal umbilical flow pattern.

In severely compromised IUGR fetuses, this pattern may predict perinatal morbidity and mortality, with a relative risk of 4 and 10.6, respectively, in babies with absent or reversed end-diastolic blood flow. These babies also have a higher risk of long-term abnormal neurological development (2).

According to the Growth Restriction Intervention Trial (GRIT), an emergency cesarean section performed on account of reversed end-diastolic blood flow does not significantly improve immediate and late prognosis and supports the need for a 24-48 hour interval to allow corticosteroid administration (2).

In a high risk population, the use of Doppler ultrasound scanning of the umbilical artery reduces perinatal morbidity and mortality. Umbilical artery Doppler should be the first-line choice for monitoring the SGA (small-for-gestational-age) fetus. If the umbilical artery Doppler is normal, the pregnancy may be monitored every two weeks (3).

When the values of umbilical artery Doppler velocimetry are abnormal and the delivery is not indicated, the fetus should be monitored twice a week to check the diastolic blood flow. Fetuses with absent or reversed end-diastolic blood flow should be examined daily (4).

The delivery of a premature SGA fetus with absent or reversed umbilical artery blood flow is recommended before 32 gestational weeks if pulsations in the umbilical vein are detected, the fetus is considered viable and steroids were administered (4).

If the SGA diagnosis was made after 32 weeks gestation and UA abnormalities were detected, the delivery should occur not later than at 37weeks gestation.

Delivery through cesarean section is recommended for SGA fetuses with absent or reversed diastolic blood flow. SGA fetuses with normal UA blood flow or abnormal UA blood flow and present diastolic blood flow may be delivered naturally, yet the rate of emergency cesarean section is high in these fetuses (4).

SGA fetuses with abnormal umbilical artery Doppler are smaller. There is a significant amount of data supporting the assumption that SGA fetuses with low umbilical artery blood flow are at higher risk of adverse perinatal outcome than normal blood flow fetuses (2).

There is a significant association between abnormal umbilical artery blood flow and perinatal outcome. Moreover, perinatal death is very rare if the umbilical blood flow is normal. Consequently, umbilical artery Doppler may be considered a tool allowing risk level differentiation in fetuses with low birth weight. Fetuses with normal Doppler ultrasound should be monitored more rarely. They may be considered normal SGA fetuses, and represent the lowest spectrum of healthy fetuses. Their

monitoring should be done accordingly (2).

There are few studies conducted during birth which compare the efficacy of CTG (cardiotocography) and Doppler, as a method able to reveal fetal distress.

Poor perinatal outcome is unusual in fetuses with IUGR and normal UA Doppler. Usually, associated diseases are present. Generally, IUGR and normal UA Doppler is a benign combination. A UA Doppler ultrasound of IUGR fetuses reduces the incidence of such obstetrical procedures as cesarean section and perinatal mortality. These fetuses are born at older gestational age and have higher average birth weight than fetuses with abnormal UA Doppler.

According to the 2014 Irish practical guidelines, IUGR fetuses with normal UA Doppler ultrasound should be monitored every two weeks and delivered between the 37 and 40 weeks gestation. These guidelines show that abnormal UA Doppler fetuses run a higher risk of adverse perinatal outcomes (5).

Middle cerebral artery (MCA) velocimety. In a premature SGA fetus, the MCA Doppler has limited accuracy for predicting acidemia and adverse outcome and should not be used to determine the time of delivery. In a term SGA fetus with normal UA Doppler, if the MCA PI value does not exceed the 5th percentile, the predictive value is moderate, but it may be considered when determining the time of fetus delivery (3).

If the MCA Doppler is abnormal, the delivery is recommended not later than 37 weeks of gestation (4).

The umbilical and cerebral flow relationship is thought to be more sensitive tool when it comes to discriminating between constitutional SGA and IUGR fetuses. Animal studies showed that this rate is rather related to the degree of hypoxia than to individual components (2).

For the IUGR fetuses, the most important decision is whether their extraction from a hostile uterine environment is more beneficial than the risks brought about by prematurity. Fetal well-being tests can be classified as chronic or acute. The former tests become progressively abnormal as hypoxia increases, and the latter are related to the acute changes that occur in the advanced stages of fetal compromise and usually precede fetal death by a few days. The test results should be correlated.

The value of cerebral Doppler for predicting adverse outcome in a general population of SGA fetuses is limited and has low sensitivity (2).

It has been suggested that near term MCA Doppler may be useful in the prediction of adverse outcome independent of UA Doppler (2).

The abnormal cerebroplacental ratio in IUGR fetuses is a useful marker able to predict severe preeclampsia and increased cesarean section rate. In late-onset IUGR this ratio is even more efficient. Both vascular tests need to be conducted in the umbilical and middle cerebral arteries (6).

The Doppler velocimetric parameters for MCA assessment are not an independent factor. Prematurity and placental insufficiency play a major role in newborn survival prognosis. The degree of cerebral circulation vasodilation does not influence survival, which seems dependent on the degree of impairment of fetoplacental circulation. Placental insufficiency is a complication involving high neonatal mortality rates, especially if the fetus is premature.

The degree of placental circulation impairment, analyzed by UA PI, influences prognosis on an independent basis. Doppler velocimetry of cerebral vascularization is

also associated with neonatal mortality. Of all the multivariate tests, prematurity and the degree of impairment of placental circulation are independent factors of the final outcome, in placental insufficiency pregnancies (7).

***Uterine artery (UtA) velocimetry*.** According to some protocols, uterine artery Doppler may be an independent IUGR criterion unlike other Doppler tests. Further research seems to be necessary before its inclusion in routine medical practice (2). We suggest performing UtA Doppler velocimetry in addition to basic ultrasonography during the 30 – 32 weeks gestation, in order to identify newborns with severe SGA (8).

***Umbilical vein (UV) velocimetry*.** A decrease in umbilical vein blood flow was also detected in an asymptomatic stage of the disease related to a decrease in placental volume (2).

***Ductus venosus (DV) velocimetry*.** Ductus venosus Doppler has moderate predictive value for acidemia and adverse outcome. It should be used to monitor premature SGA fetuses with umbilical artery abnormalities and to determine the time of delivery (4).

Umbilical blood tests are considered the gold standard for the assessment of newborn condition. The acid-base balance at delivery is more accurate than the Apgar score for the detection of intrapartum asphyxiation. There are undeniable connections between acidosis at birth and venous Doppler alterations, which account for the use of this method when making decisions to induce labor.

In conclusion, abnormal DV velocimetry is more common in high risk pregnancies than UA or MCA velocimetry. DV RI seems to be a better perinatal outcome predictor than the MCA S/D ratio (9).

Umbilical venous blood flow could be considered a more direct and physiological measurement of placental vascular function than that of umbilical artery Doppler indices because it indirectly reflects the amount of oxygen and nutrients reaching the fetus. Intrapartum UA Doppler is a poor predictor of the obstetrical outcome.

In normal circumstances, 20-30% of the umbilical vein blood passes the liver and is shunted through the ductus venosus to supply blood to the fetal heart and brain. In cases of chronic hypoxia, the ductus venosus is dilated and the amount of shunted blood increases to maintain adequate vital organ oxygenation. Consequently, diastolic blood flow velocimetry in the ductus venosus is the first parameter to be impaired by fetal hypoxia, followed by pulsations in the intra-abdominal part of the umbilical vein.

In conclusion, intrapartum CTG and UV Doppler monitoring may provide additional information in high risk pregnancies about the fetal condition and any suspected intrapartum fetal hypoxia (10).

Fetuses delivered through emergency cesarean section for suspected fetal distress had the lowest umbilical venous blood flow rates. If this blood flow is diminished, the cesarean section rate is higher and the relative risk is 2.83 times higher than in those with normal flows. Poorer outcome is also noted after birth. Measuring the umbilical venous flow may contribute to a hierarchical classification of pregnancy risk before delivery. The flow is calculated by multiplying blood velocity with vein diameter (11).

Biophysical score (BPS). Doppler abnormalities occurring in several vessels before 34 weeks gestation foresee an abnormal biophysical score and, hence, intra-

uterine death. After 34 weeks gestation death after abnormal MCA occurs faster than death predicted by the biophysical score. Fetal compromise progresses from placental to cerebral abnormalities, then to venous circulation abnormalities and only later to an abnormal biophysical score (12).

The median interval between a low MCA PI and death is 5 days. Fetus follow-up two times a week seems reasonable. The BPS becomes abnormal too late and it is not useful for indicating follow-up intervals. The BPS is slightly more useful before 34 weeks gestation f or determining the follow-up intervals in SGA fetuses in order to prevent fetal death. After 34 weeks gestation, MCA Doppler is the only parameter employed to set the fetal follow-up intervals (12).

Obstetric management. Unless other problems occur, normal SGA fetuses, the average umbilical and cerebral artery Doppler values of whom are normal, may be delivered naturally, under surveillance, yet before 40 weeks gestation.

Normal IUGR fetuses with abnormal cerebroplacental ratio (CPR) but without uterine artery Doppler changes are recommended a Doppler ultrasound two times a week and natural delivery after 37weeks gestation.

The obstetric management in the IUGR fetuses with abnormal cerebroplacental ratio or abnormal uterine artery Doppler and absent end-diastolic blood flow in the umbilical artery depends on their gestational age.

After 34 weeks gestation they may be delivered naturally, but in case of absent diastolic flow by cesarean section. Between 32 and 34 gestational weeks, reversed end-diastolic flow – corticosteroids and cesarean section within 24-48 hours; absent end-diastolic flow, steroids, daily Doppler ultrasound and delivery after 34 weeks gestation. Before 32 weeks – steroids and daily Doppler ultrasound until 34 weeks (2).

The IUGR fetuses with abnormal cerebroplacental ratio or uterine artery Doppler flow, with persistent ductus venosus pulsatility and abnormal biophysical profile: beyond 32 weeks – cesarean section, bellow 32 weeks – steroids, admissio, daily Doppler ultrasound until 32 weeka.

The IUGR fetuses with abnormal cerebral and uterine Doppler ultrasounds and decompensation – cesarean section at a tertiary care center. In those under 28 weeks, each case should be assessed by a multidisciplinary team. The family has also to be consulted (2).

Babies' outcome. The fetoplacental relationship is most strongly impaired during the intrapartum period. Uterine contractions may reduce by up to 60% the blood flow in the uterine arteries, and reduced placental perfusion may cause fetal distress. About 14.5% of the cases of neonatal cerebral palsy and encephalopathy are associated with intrapartum hypoxia. In developed countries, hypoxic-ischemic encephalopathy occurs in 2-3 out of 1000 live newborns, whereas in developing countries, the incidence is 10 times higher. Up to 63% of intrapartum hypoxia cases occur in pregnancies with no antenatal risk factors. The cerebroplacental (C/U) ratio analysis in term babies from low risk pregnancies before active delivery may predict a diagnosis of intrapartum fetal distress and the need for emergency cesarean section (13).

Correlations. In a study conducted in Ireland and published in AJOG in 2014, 76% of the 1200 IUGR pregnancies required active decision making regarding the mode and timing of delivery. Forty

percent required pre-labor cesarean section and 11% of them had abnormal Doppler velocimetry as delivery indication (14).

The cesarean section rate for suspected fetal distress was higher in normal weight and low cerebroplacental ratio fetuses than in SGA and normal CPR fetuses, which proves that CPR is more commonly associated with fetal distress than birth weight. Only SGA fetuses with abnormal CPR were admitted to a neonatal emergency unit (NNU) more frequently. Neonatologists are more prone to admit babies to NNU if they are younger (15).

Stratification of birth outcomes is more accurate using Doppler indices than newborn weight. The study supports the assumption according to which normal weight babies may also be compromised due to placental insufficiency and recommends Doppler ultrasounds in all of them. Most national guidelines recommend Doppler ultrasound only in complicated SGA pregnancies and not in normal weight babies (15).

The C/U ratio was often used in SGA studies. It seems it was the first time when it was used in normal weight and term babies. All those in the 90th percentile had no problems at birth and did not require emergency cesarean section.

The effect is independent of parity, gestation, birthweight and mother BMI. The technique should be generalized in order to classify pregnancies before delivery (13).

CONCLUSIONS

In our obstetrical experience, Doppler follow-up of IUGR babies is a good indicator of their health and may help the decision making for a caesarian section.

According to a particular protocol this method slightly reduces the cesarean section rate and decreases premature birth frequency (16): the absent or reversed blood flow in the umbilical artery is the most efficient cesarean section indicator; the MCA flow is more reliable in near-term pregnancy; the biophysical score is more reliable at younger gestational ages; ductus venosus examination often helps; some authors suggest that umbilical vein blood flow should be measured in all pregnancies; sometimes, uterine artery velocimetry is also necessary; measurements of various vascular systems should be correlated and an overall integrative score should be developed.

IMPACT OF BACTERIAL CELLS AND SECRETOMES ON WOUND HEALING

According to Brothers KM *et al.*, bacterial cells and secretomes from *Serratia marcescens (*95%), *Pseudomonas aeruginosa* (71%) and *Staphylococcus aureus* (29%) strains inhibit human corneal epithelial cell migration *in vitro* and *ex vivo*, thus affecting the process of wound healing. Lipopolysaccharide (LPS) seems to be a key factor in this inhibitory mechanism, since LPS core biosynthetic genes are required to inhibit corneal epithelial cell migration. Purified LPS from *S. marcescens* inhibits epithelial cell migration *in vitro* and wound healing *ex vivo*, while after LPS depletion of *S. marcescens* secretomes, migration of epithelial cells was no longer inhibited, suggesting that *S. marcescens* LPS is sufficient for inhibition of epithelial wound healing (Brothers KM, Stella NA, Hunt KM, Romanowski EG, Liu X, Klarlund JK, et al. Putting on the brakes: Bacterial impediment of wound healing. Sci Rep. 2015;5:14003. doi: 10.1038/srep14003).

ATYPICAL PRIMARY HYPERPARATHYROIDISM DUE TO HYPOVITAMINOSIS D (Abstract): Vitamin D deficiency is nowadays very common in the general population and also in patients with primary hyperparathyroidism. Hypovitaminosis D may modify the clinical features and the severity of primary hyperparathyroidism. We present the case of a 75-year-old woman with a 10 year history of nephrolithiasis and severe osteoporosis, with multiple fragility fractures. Her bone and kidney status required a more thorough metabolic assessment. Despite minimal changes in serum calcium and phosphate levels, parathyroid hormone (PTH) level was markedly elevated. Ultrasound and specific Sesta-MIBI scintigraphy diagnosed and localized a left parathyroid adenoma. Vitamin D assessment showed levels in the range of hypovitaminosis. Vitamin D deficiency may mask hypercalcemia despite high serum PTH levels, and does not seem to diminish but on the contrary increases the risk of kidney lithiasis, as well as the deleterious effects of hyperparathyroidism on bone. **Keywords:** PRIMARY HYPERPARATHYROIDISM, VITAMIN D, PARATHYROID HORMONE.

Primary hyperparathyroidism (hPTH) is currently considered one of the most common endocrine diseases, with a prevalence reaching 1-2% among women aged over 50 (1). Excessive parathyroid hormone (PTH) secretion may be deleterious due to massive bone demineralization and severe hypercalcemia accompanied by a higher risk of kidney lithiasis and soft tissue calcification. However, the spectrum of severity of hPTH has widely changed in recent decades, especially since milder forms are diagnosed by routine calcium measurement, cervical ultrasound and bone mineral density assessed by Dual X-ray absorptiometry (DXA).

PTH and vitamin D are known to be the two major regulators of calcium and bone metabolism, the two hormones having direct interferences. PTH activates vitamin D to 1,25(OH)2D3 in the kidney by stimulating 1-alpha hydroxylase. Active intestinal calcium absorption is directly stimulated by 1,25(OH)2D3. At its turn, 1,25(OH)2D3 downregulates PTH secretion by direct effects on the parathyroid glands (2).

The increase of life span and the decrease of sunlight exposure due to modern

life caused a vitamin D deficiency epidemic in the general population. Interestingly, vitamin D deficiency was found by several authors to be more common in patients with primary hPTH than in the general population (3,4,5). The consequences of vitamin D deficiency in these patients and its appropriate management are unclear. We present the case of a 75-year-old woman diagnosed with primary hPTH and vitamin D deficiency.

CASE REPORT

BG, a 75-year-old woman was admitted to the Endocrinology Department of "St. Spiridon" Hospital for the metabolic investigation of severe osteoporosis with multiple pathological fractures. Our third age patient had a body weight in the lean range (BMI = 21 kg/m2), therefore the presence of osteoporosis was not a surprise. However, the patient had a profoundly decreased bone mineral density (BMD) evaluated by DXA in all locations, with the lowest T-score found at the distal 1/3 of the radius (Table I), highly suggestive of primary hPTH. Anamnesis revealed not only a 10-year history of multiple fractures, but also relapsing nephrolithiasis for which she underwent several sessions of extracorporeal shockwave lithotripsy, increasing our suspicion of primary hPTH. However, serum calcium and phosphate were only mildly out of the normal range (Table II).

TABLE I

Bone mineral density assessed by Dual X-ray absorptiometry

	T-score	BMD (g/cm^2)
LUMBAR	-4.4	0.635
hip	-3.7	0.491
forearm	-5.4	0.371

The association of "stones and bones" complications raised the suspicion of primary hPTH. In contrast with the important skeletal and kidney impact, the metabolic profile of our patient showed only mild hypercalcemia (10.78 mg/dl) and hypophosphatemia (2.25 mg/dl), albeit significant hypercalciuria (408 mg/24h). The measurement of PTH revealed an elevated level (228 pg/ml). Renal function of our patient was intact: urea 36 mg/dl (reference range 21-43 mg/dl), creatinine 0.82 mg/dl (reference range 0.57-1.11 mg/dl). The discrepancy between the mild changes in serum calcium and phosphate and the marked increase in serum PTH level made us evaluate vitamin D levels that were found decreased (10.59 ng/ml) (tab. II).

TABLE II

Comparison between metabolic parameters

Normal ranges	2013	2014
Calcium 8.8-10.2 mg/dl	10.78	10.89
Phosphate 2.5-4.7 mg/dl	2.25	2.2
Calciuria 100-300 mg/24h	408	445
PTH 15-65pg/ml	228	242
25-OH-D >30 ng/ml	10.59	-

Neck ultrasound revealed a hypoechogenic nodule, posterior to the left thyroid lobe, measuring 1.6x0.8cm, with peripheral vascularization (fig. 1). The specific scintigraphic investigation showed increased uptake of Technetium (Tc) 99m Sestamibi (MIBI) in the suspected nodule, localizing a left parathyroid adenoma (fig. 2).

The patient was advised to undergo a minimally invasive approach to remove the

abnormal parathyroid gland, under protection by bisphosphonate therapy (alendronate, 70 mg/week) and vitamin D supplementation. The patient did not present, however, to the Surgery Department as scheduled.

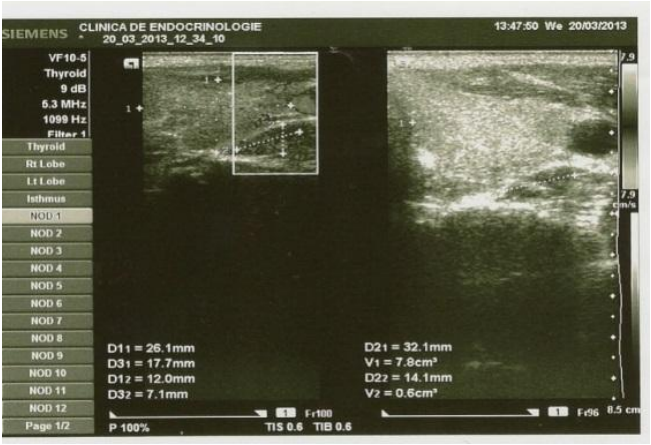

Fig. 1. Cervical ultrasound showing a left parathyroid adenoma

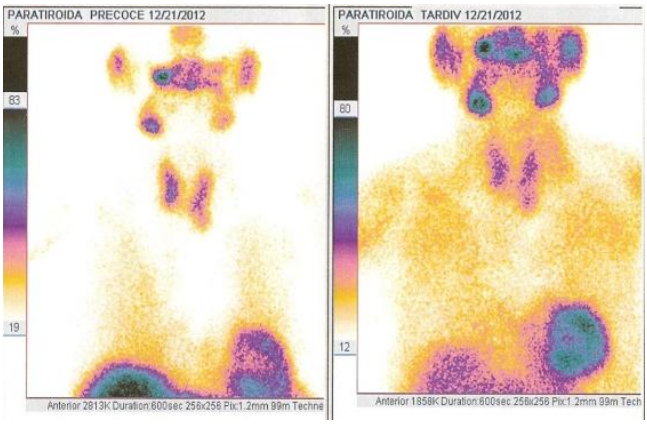

Fig. 2. Scintigraphic investigation, localization of a nodule posterior to the left thyroid gland

The patient presented to our Department for another check-up in January 2014, with a somewhat aggravated metabolic profile (tab. II). 25-OH-D level was not reassessed, but vitamin D supplements were not taken. Despite persistence of primary hPTH, DXA revealed a general increase in BMD following antiresorptive treatment (Lumbar T-score -3.1; Hip T-score -2.7; Forearm T-score -5.1) (fig. 3).

The patient underwent a left inferior parathyroidectomy with the excision of a parathyroid adenoma with a maximum diameter of 1.6 cm (fig. 3). Immediately after excision, PTH dropped to a normal level of 22 pg/ml, confirming an excessive PTH secretion.

The patient had a favorable outcome af-

ter surgery, with phosphocalcic parameters within normal range after just one day (calcium 9.03 mg/dl, phosphate 3.46 mg/dl, PTH 13.11 pg/ml).

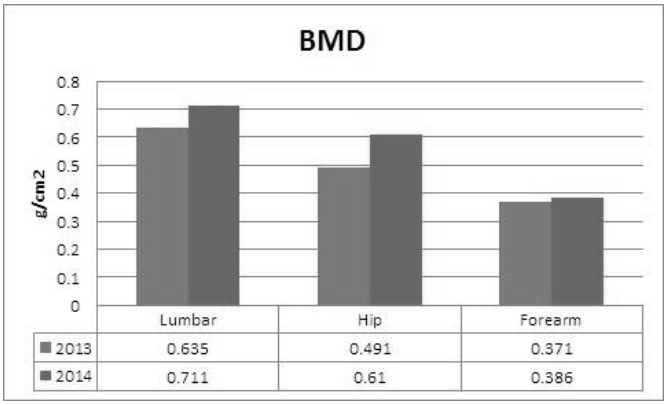

Fig. 3. BMD improvement after one year of treatment

Fig. 3. Left inferior parathyroid adenoma

DISCUSSION

Primary hPTH is usually accompanied by hypercalcemia, hypophosphatemia and increased_vitamin D level due to excessive 1-alpha hydroxylase activation by PTH. Co-existence of hypovitaminosis D in hPTH may decrease the active intestinal calcium absorption, thereby diminishing serum electrolyte changes (3, 5). Hypovitaminosis D may also contribute to a further tumor growth and increase in PTH secretion due to lower calcium and vitamin D levels and to a consecutive decrease of the negative feedback exerted on the parathyroid adenoma

(3,6-9). This leads to a vicious circle, worsening the renal and bone changes (9, 10, 11).

The higher incidence of hypovitaminosis D in hyperparathyroidism could be explained by several hypotheses. Due to lack of negative feedback, low vitamin D levels may favor the development of an autonomous parathyroid gland, with subsequent occurrence of hyperplasia and adenoma transformation, or accelerated course of a preexisting adenoma (12). PTH-mediated increase of $1,25(OH)_2D$ may alternately reduce 25(OH)D levels by inhibiting the hepatic synthesis of vitamin D (3) .

In our case, hypovitaminosis D partially masked the typical serum metabolic profile of primary hyperparathyroidism, but did not impede the deleterious impact of hPTH on bone loss and kidney stone formation. Delay in diagnosis was also influenced by the additional risk factors for osteoporosis in our patient (age, sex, body mass). PTH tends to be, however, more catabolic at cortical sites, especially at the distal 1/3 of the radius, and this particular modification was also observed in our patient. The association of severe osteoporosis and relapsing renal lithiasis with hypercalciuria increased the suspicion of primary hyperparathyroidism. Despite the persistence of primary hyperparathyroidism, therapy with bisphosphonates had protective effects on bone, but did not diminish PTH levels or improve the metabolic profile of our patient.

CONCLUSIONS

Our case report highlights that when hypovitaminosis D is associated with hyperparathyroidism it masks hypercalcemia, but may aggravate the deleterious effects of the disease on bone loss and on kidney stone formation, so any patient with relapsing lithiasis and/or disproportionately severe osteoporosis should be suspected of primary hyperparathyroidism; if the metabolic parameters are only slightly modified, vitamin D deficiency should be suspected. Vitamin D supplementation in these patients remains a question of debate.

TOPICAL METHOTREXATE FORMULATION FOR PSORIASIS TREATMENT

Psoriasis, a chronic inflammatory skin disease, affects 1 to 3% of the world population. The therapeutic agents used in the treatment of this disease are corticosteroids, dithranol, salicylic acid and vitamin D analogues. The nanostructured lipid carriers (NLCs) play an important role in targeting the drug to the skin. In order to obtain new topical formulations for the treatment of psoriasis, NLCs were used for incorporation of methotrexate. The formulations contained methotrexate, Witepsol S51, oleic acid, Polysorbate 60 (MTX_NLC-P60) or Polysorbate 80 (MTX_NLC-P80). The formulations were tested for their stability by measuring the particle size, the surface charge and the amount of MTX after storage at 25°C for 28 days. Scanning electron microscopy was used to study surface morphology. All formulations showed a high physical stability. *In vitro* skin permeation was evaluated using a Franz cell. The results revealed an increased penetration of MTX_NLC-P60 (5.8 ± 0.2%) and MTX_NLC-P80 (4.2 ± 0.1%) as compared to free MTX (3.6 ± 0.2%). *In vitro* evaluation of drug release from both formulations in a simulated physiological environment showed a quick initial phase of drug release (64%) in the first 2 h, followed by a sustained release until 8 h. The study revealed the potential use of NLCs in the development of topical formulations for psoriasis treatment (Pinto MF, Moura CC, Nunes C, Segundo M *et al*. A new topical formulation for psoriasis: development of methotrexate-loaded nanostructured lipid carriers. *Int J Pharm* 2014; 477 (1-2): 519-526).

COEXISTENCE OF CELIAC DISEASE AND SYSTEMIC LUPUS ERYTHEMATOSUS IN A 6-YEAR-OLD GIRL-CASE REPORT

Geanina Irina Crişcov*, A.B. Stana, Ileana Katerina Ioniuc, Mihaela Monica Alexoae, Evelina Moraru

COEXISTENCE OF CELIAC DISEASE AND SYSTEMIC LUPUS ERYTHEMATOSUS IN A 6-YEAR-OLD GIRL (A CASE REPORT) (Abstract): Systemic lupus erythematosus (SLE) is a serious and potentially fatal syndrome characterized by an autoimmune assault on various organs and systems that may include the skin, joints, central nervous system, heart and kidneys. Recent research shows that gluten sensitivity causes more than just celiac disease and gluten has been linked to numerous autoimmune conditions. We report here a 6-year-old girl presenting with malaise, abdominal pain, loss of appetite, abdominal distension. After three weeks she developed other symptoms such as arthralgias, malar rash, being finally diagnosed with SLE and possible autoimmune hepatitis. The suspicion of celiac disease was based on a combination of symptoms (poor growth, iron deficiency anemia, chronic abdominal pain, abdominal distension, constipation, "sad child"), IgA deficiency, in the presence of SLE diagnosis. Positive diagnosis of celiac disease was confirmed by the presence of an anti IgG anti-transglutaminase antibodies titer of 120 EU/ml (normally less than 20 EU/ml). Small bowel biopsy showed a IIIB1 stage according to the Marsh classification. Three methylprednisolone pulses were promptly administered, followed by oral prednisone (2 mg/kgbw/day) with a good outcome.
Keywords: SYSTEMIC LUPUS ERYTHEMATOSUS, PEDIATRIC CELIAC DISEASE, AUTOIMMUNE HEPATITIS, OVERLAP SYNDROME

Systemic lupus erythematosus is an autoimmune disease characterized by auto antibodies directed against self antigens, immune complex formation and immune disturbances which may affect joints, skin, kidneys, heart, lungs, the nervous system and the immune system (1). Children generally have a more severe disease onset and progression than adults (2, 3).

The disease is more common in girls and is quite rare under the age of 6 years. Diagnosing SLE in children is usually problematic. It was previously believed that the association between celiac disease (CD) and SLE is rare and uncertain (4). However their coexistence was proved by showing that both diseases have an autoimmune origin and share human leukocyte antigen (HLA)-B8 and histocompatibility antigen (HLA)-DR3 (5).

The manifestation of Celiac disease can occur before or after the diagnosis of lupus (6). The description of overlap syndromes

in terms of auto antibodies is based on the assumption that the pattern of autoimmunity reflects the underlying cause for the disease (7).

We present a severe case of a young patient who was diagnosed with overlap syndrome: SLE, celiac disease and hepatitis.

CASE REPORT

We report the case of a 6-year-old girl who presented with malaise and abdominal pain. She had no chronic medical conditions and no significant family history of medical illnesses. Before the onset of symptoms she was in good health but her mother complained about poor weight gain and constipation. She also had stated that her daughter was always a "sad child".

Current disease history stands ten days before admission with malaise, fatigue, pale skin, abdominal pain and loss of appetite. On physical examination, the patient was in obvious discomfort, her body temperature was 37°C, her skin was pale with discrete jaundice, nutritional status revealed a low weight for age (2 standard deviations for normal weight), her blood pressure was normal but a systolic murmur was detected. Further on, full clinical exam revealed hepatosplenomegaly, no palpable lymphadenopathies or abdominal bloating.

The laboratory testing revealed normal white blood cell (WBC) count of 6.88 × 103/μL, moderate anemia with red blood cells (RBC) count of 3.05 × 106/μL, a hematocrit of 24.9%, hemoglobin level of 7.6 g/dL and platelet counts of 320× 103/μL. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were elevated (AST=1641 U/L, ALT=1554 U/L), indirect hyperbilirubinemia at 2.03 mg/dL was also detected. Liver functional involvement syndromes revealed low fibrinogen values of 179 mg/dL (normal between 200-400 mg/dL), low albumin values of 37% (normal between 53.5-66.5%), elongated TQ of 21.7 seconds (normal between 13-17 seconds), hypergammaglobulinemia of 42% and no abnormal bilioexcretory syndrome. Acute and chronic liver diseases were ruled out by negative serologies for viral hepatitis A, B, C, cytomegalovirus (CMV) and Epstein-Barr virus (EBV); also human immunodeficiency virus (HIV) infection was ruled out by negative serologies. An abdominal ultrasound was performed and it showed hepato-spleno-megaly without deep lymphadenopathy.

She promptly received arginine (10mL/kgbw/day) as hepatoprotective perfusions. Meanwhile we excluded metabolic hepatitis, alpha-1-antitrypsin deficiency, Wilson's disease (ceruloplasmin, cupruria and cupremia with normal values), cystic fibrosis (iontophoresis with values of 25 mmol/L NaCl). She had a very high erythrocyte sedimentation rate (ESR) of 138mm/h and a positive C-reactive protein (CRP).

Anemia associated with indirect hyperbilirubinemia imposed investigations for a possible hemolytic anemia; reticulocytes were increased (5%), but globular resistance, autohemolisis and alkali-resistant hemoglobin were all within normal ranges. The Coombs test was positive, confirming autoimmune hemolytic anemia. We also evaluated serum iron with low values of 25 μmol/L, total iron-binding capacity (TIBC) of 455 μg/dL (normal 228-428 μg/dL), and serum ferritin of 20 ng/mL (normal values between 13-150 ng/mL). Bone marrow aspiration and biopsy showed all three cell line elements without evidence of malignancy.

As a result of these investigations we

suspected an autoimmune disorder. Immunological profile revealed a positive value of antinuclear antibodies (AAN) 1 index (negative <0.7 index), the antideoxyribonucleic acid antibodies (dsDNA) positive titers, with high values of 120.4 IU/mL (negative <10), a normal complement C'3 fraction 99 mg/dL (normal between 90-180 mg/dL), a negative titer of anti-LKM 1 antibodies (liver-kidney microsome) and anti-smooth muscle antibodies and absence of SLE cells and cryo-globulins.

Other immunological investigations have revealed immunoglobulin A (IgA) deficiency of 20.37mg/dL(normal 91-255 mg/dL), hyper IgG of 6824.15 mg/dL (normal 850-1300 mg/dL) and normal levels of IgM.

The result of renal function tests were in the normal range (serum urea 30 mg/dL, serum creatinine 0.72 mg/dL). No microscopic hematuria or proteinuria was detected. Also serum glucose, amylases and cholesterol were on normal range but triglycerides are elevated values of 165 mg/dL (normal 40-135 mg/dL).

During her three-week hospitalization her symptoms gradually worsened and other important elements occurred: malar rash and arthralgia in the small joints of the hands, without local inflammatory phenomena. We performed a chest X-ray for exclusion of TB infection and an echocardiography who revealed normal structure and function of the heart with minimal presence of pericardial reaction.

Finally positive lupus diagnosis was based on 6 of the 11 required ACR criteria: "butterfly rash", arthritis, serositis (pericarditis), hematological disorder: autoimmune anemia, immunological changes as SLE cells, antideoxyribonucleic acid antibodies (dsDNA) positive titers and positive antinuclear antibodies (ANA).

Because the patient maintained unexplained abdominal distension in the context of the existence of an autoimmune disease we considered necessary to perform further investigations for other autoimmune disorder. We detected an elevated level of antitransglutaminase IgG antibody titer of 120 EU/ml (normal less than 20 EU/ml); IgA antritransglutaminase antibodies were negative. The small bowel biopsy result revealed a IIIB1 stage according to the Marsh classification.

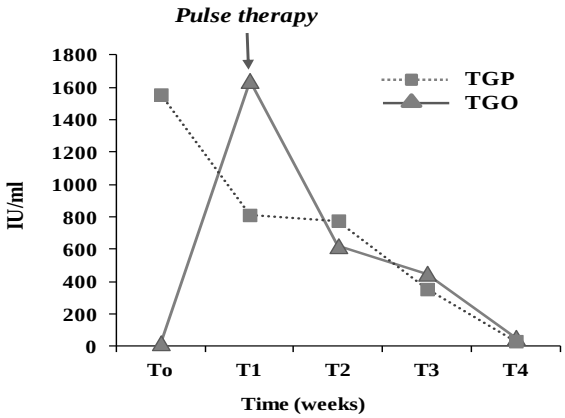

Fig. 1. Evolution of transaminases; TGO and TGP liver enzymes decreased significantly after initiating pulse therapy.

We initiated the treatment with corticosteroids, three methylprednisolone pulses (1 g/1.73 m2 per day) and gluten free diet. Patient's response to steroid along with gluten-free diet was excellent, with a significant decrease of liver enzymes (TGO and TGP) (Fig. 1), ESR (26 mm/h) and improvement of Hb to 8.8 g/dL. After that she was treated with oral Prednisone (2 mg/kgbw/day).

The particularity of this case consists in the complexity onset, with accompanying hepatitis, young age and the association of other autoimmune disorders: celiac disease and hepatitis

DISCUSSION

SLE is one of the most diverse autoimmune diseases as it may affect more organs in the body. It has a broad spectrum of clinical and immunological manifestations (1, 8).

Nowadays, among people with lupus "overlapping" autoimmune conditions, including celiac disease, are common. On the other hand, according to statistics, patients diagnosed with celiac disease will be diagnosed with other autoimmune diseases in their lifetime: collagen vascular disease, type 1 diabetes, rheumatoid arthritis, Sjögren's syndrome, liver disease (2, 9).

People with celiac disease face three-times higher risk of SLE compared to the general population (10).

Celiac disease is a multifactorial, autoimmune disorder that occurs in genetically susceptible individuals. It is triggered by an environmental factor-gluten (11). Testing for CD should be performed in children with unexplained poor growth, iron deficiency anemia, chronic abdominal pain, constipation, and abnormal liver biochemistry, symptoms that our patient has showed (12).

Serological diagnostic based on determination of autoantibodies against transglutaminase type 2 (TG2) and endomysial antibodies (EMA) and can be confirmed by result of small bowel biopsy and HLA serotyping (11). HLA testing should be performed in cases where there is an uncertain diagnosis of CD (cases with negative CD specific antibodies and mild changes on proximal small intestinal biopsy) (4).

In our case the suspicion of celiac disease was based on combination of symptoms (poor growth, iron deficiency anemia, chronic abdominal pain, abdominal distension, constipation, "sad child"), immunological changes (IgA deficiency) and the presence of other autoimmune diseases.

It is also important to test total serum IgA to be able to interpret the IgA anti-TG2 result (as IgA deficiency is more frequent in patients with CD) and, in those individuals with IgA deficiency, IgG TG2 antibodies may be used (although these are less specific).

In our case with IgA deficiency was necessary to use IgG TG2 antibodies; it was not necessary to carry out HLA serotyping because the biopsy was conclusive.

In practice, the diagnosis of an overlap syndrome makes little difference to treatment although the detection of an autoantibody does help the clinician to anticipate particular complications (13).

Management of SLE in children is challenging (9). The unpredictability of the disease, with remissions and relapses, can be difficult for the family and child and for doctors. Corticosteroids are the mainstay of treatment (14).

Most of the children will also require additional medications depending on organ involvement. However, investigations and treatment should not be delayed until these criteria are fulfilled. Our patient requires careful, long-term follow-up and should adopt a gluten-free diet to avoid future complications of the condition.

CIRCULATING TUMOR CELLS IN RECTAL CANCER PATIENTS-A REVIEW OF THE LITERATURE (Abstract): Rectal cancer treatment has been continuously improving in the past decades and research has rightly been directed for this purpose, because this is a major public health issue. On the other hand, circulating tumor cells have emerged in the past two decades as an important element in oncology, because of the large potential they offer. They have been studied mostly in breast cancer and have already been implemented as a tool in certain strategies in this field. Thus, circulating tumor cells in rectal cancer may have the same important applicability, with a wide range of usages, from screening to diagnostics, guidance of the treatment and even follow-up. This article aims to review the literature and exhibit data about the pathophysiology, utility and methods of identification of circulating tumor cells with focus on their link to rectal cancer. **Keywords:** RECTAL CANCER, CIRCULATING TUMOR CELLS.

The importance of rectal cancer resides both in its high incidence, as well as in the complexity of the treatment, that relies in most cases on a multidisciplinary team, being a multimodal approach.

Circulating tumor cells (CTCs) are an innovative field in oncology. This subject is widely investigated in the recent years and is of great interest in the research field due to the various advantages of studying the tumor cells in the blood stream. These cells can derive either from the primary tumor, or from its metastases, thus being an important marker in evaluating the prognostic of the disease, monitoring the response to certain therapies, or selecting patients as targets for certain therapies (1).

Rectal cancer, an important public health issue and its connection to circulating tumor cells

According to the Globocan 2012 study, colorectal cancer is the second neoplasia in incidence in both sexes, both in Romania and within the European Union. On a global scale, it is situated in incidence after pulmonary and breast cancer. The incidence of 13.1%, the 5-year prevalence of 13.3%, as well as a 11.9% rate of mortality make it an important public health issue, especially in developed countries.

With all these aspects aside, the mortality through this type of cancer is on a

descending trend in most developed regions. All this thanks to the increase in national and local screening programs, due to the increase in the efficiency of the diagnostic methods, and because of the improvements brought to treatment methods (2).

Screening in rectal cancer is one method of decreasing mortality, through an early diagnostic and the opportunity yielded by precocious identification of potentially malignant lesions or preneoplastic polyps. The clinical practice guidelines elaborated by the National Comprehensive Cancer Network (NCCN) serve as tools to direct the clinician towards this endpoint. Although not applied on a national level now in Romania, these guidelines setup a consensus between colorectal cancer specialists, that can be taken into consideration when aiming for a precocious diagnosis and a suitable treatment (3).

Bearing this aspect in mind, two categories of screening tests arise: structural tests and stool-based tests.

Structural tests give the possibility of identifying incipient lesions or even polyps that have the potential of malignant transformation. These tests are based on imaging-colonoscopy and radiology. Rigid rectoscopy, rectosigmoidoscopy, colonoscopy, barium enema and computed-tomography (which gives the possibility of obtaining a virtual colonoscopy) are the methods included in this category, which are, of course, invasive, with risks that increase with age and associated morbidities (4).

On the other hand, stool-based tests, consisting of the fecal occult blood test, the fecal immunochemical test and the detection of altered DNA, have the advantage of non-invasiveness, but are, on the other hand, poor in means of specificity; the probability of detection of adenomatous polyps is low. The immunochemical test brings an improvement in the matter of sensitivity (5, 6) and the DNA testing is the best of the non-invasive methods in means of sensitivity but lacking in the mater of cost-effectiveness (7).

All in all, the gold standard for colorectal cancer screening is the colonoscopy, with great advantage of providing a biopsy in given cases. Moreover, a positive non-invasive test will lead to a colonoscopy evaluation (3).

Another factor that aims to improve mortality rates is the treatment and its continuous developments. The multidisciplinary approach, based on the decisions taken by a complex team of specialists aims to individualize the treatment based on the characteristics of each patient. On this subject, a sequential treatment plan is taken into discussion; the decision to apply a neoadjuvant treatment or opt for upfront surgery is based on the extent of the tumor, set up by imaging means. The efficiency of neoadjuvant radio chemotherapy on rectal cancer has been demonstrated through various trials, becoming routine in locally advanced, non-metastatic tumors (8, 9). However, some tumors respond well to neoadjuvant treatment, whereas others do not, with a stationary or even progressive status after the long-term scheme of neoadjuvant radiotherapy, with a considerable amount of time lost in the detriment of the patient. Therefore, additional predictive factors for the neoadjuvant treatment must be developed to reduce this setback. CTCs may play an important role in this matter, providing the examiners with important information.

The adjuvant treatment in rectal cancer is based on the prognostic value of the

tumor staging, along with additional factors, such as microsatellite instability, tumor budding, circumferential resection margins, perineural invasion, tumor regression grade, and K-ras genotype. However, bearing in mind the actual tendency of treatment individualization, other factors are studied, to provide access to the best therapeutic option. CTCs might have an important role in this aspect as well.

Circulating tumor cells and their presence in the body

CTCs are cells of tumor origin that are released into the blood stream. Even if they were identified and described over one century ago, in 1869, they became a domain of interest approximately one decade ago, when studies performed on CTCs, methods of identifying and counting them began to flourish in oncology (10). They are considered the main mechanism of metastasis, thus studying them contributing to a better understanding of the metastasis cascade and helping better the treatment of the oncologic disease (11). Moreover, there is the notion of disseminated tumor cells (DTCs), that result from the embedding of CTCs in a metastasis site (12).

CTCs are rare in the patient's bloodstream - 1 to every $10^6/10^7$ circulating mononuclear cells. Studies from 1975 mention a quantity of one million tumor cells released per each gram of the tumor (13). However, this number is overrated, bearing in mind the conditions in which CTCs are released into the bloodstream and the half-life of these cells within the bloodstream.

The modality in which they leave the tumor site varies: either single or in clusters - clusters can be homotypic or heterotypic (14, 15). Depending on their properties, there are different characteristics specific to each category. Thus, single CTCs are more frequent in the bloodstream, with a good chance of penetrating small vessels, but have the downside of having a high risk of apoptosis, with low chances of metastasis formation. On the other hand, clusters are rarer, but have higher chances of metastasizing due to the lower risk of apoptosis and the fact that they already have their own formed microclimate. Although many aspects about CTCs and DTCs are yet unknown, one particularity is clear: the phenotypic plasticity, manifested in the high possibility of phenotypic changes to "survive" (15).

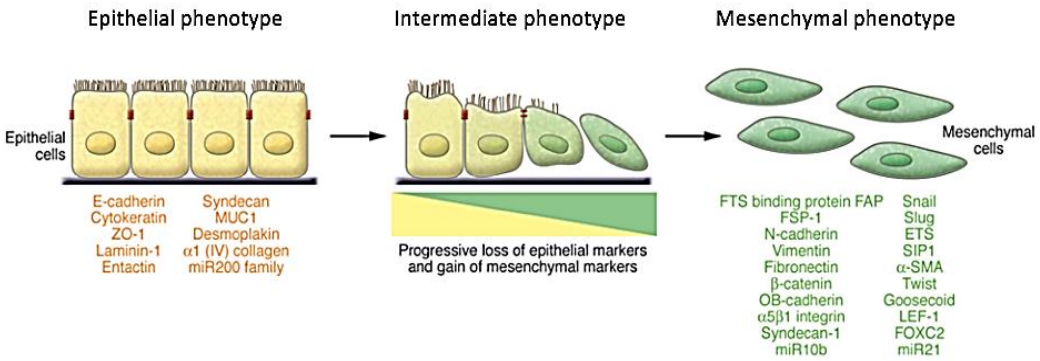

Fig. 1. Epithelial-mesenchymal transition (reproduction after Kalluri R, Weinberg RA. The basics of epithelial-mesenchymal transition. *JCI* 2009; 119(6): 1420-1428)

The efficiency of a CTC or DTC is given by its capacity to metastasize. For this event to take place, these cells need to undergo changes that increase their invasive capacity (16, 17).

Carcinomas are the most frequent type of neoplasia, deriving from epithelial cells from different organs. Under certain mutagen factors, the cells comprising the normal tissue lose their apico-basal polarity along other phenotypes, such as growth control and become adenomas. In time, these abnormal cells become in situ carcinoma, with properties that make it malignant (16).

Up next, these malignant cells undergo changes that are essential for obtaining the ability of invasion and metastasizing. Normally, cells are linked to the basement membrane by molecules such as E-cadherin, plakoglobin and integrins. In special situations, such as organogenesis and tissue repair, these cells obtain the capability of detaching from the basement membrane. Oncogenesis and metastasis also imply the occurrence of this event, in which the above-mentioned proteins are replaced by vimentin and N-cadherin; it is this change that determines the exposure of detached cells to the stromal fibroblasts, leucocytes, extracellular matrix and neoformation vessels. This event is called epithelial-mesenchymal transition (EMT) (fig. 4) (18).

The primary tumor may contain cells in different steps of this transition, thus expressing different characteristics; they may be included in two categories (12):

1. A mesenchymal-like form, with receptors to adhere to the extracellular matrix. These cells produce enzymes such as metalo-proteinase that permit the progression of the tumor through: degradation of the extracellular matrix and of the intercellular junctions, stimulation of cell motility and EMT. These cells may be thought as the promoters of cellular invasion, by creating an adequate microenvironment for this event.

2. An amoeboid form, with cells with high plasticity, that can easily pass through the gaps in the basal membrane made by the above-mentioned cells.

On the other hand, once released in the bloodstream, the tumor cells can have three types of evolution (19):

1. The first situation is when cells are released into the bloodstream, once detached from the extracellular matrix and, in the absence of a propitious microenvironment, they either suffer anoikis, apoptosis or necrosis, being annihilated, finally, by the immune system. Obviously, this is unproductive prim the metastasis point of view.

2. The second type of evolution is represented by cells that have reached a metastatic target and remain in this site in a G0 phase of the cell cycle, dormant, with an equilibrium between proliferation and apoptosis, thus being a temporary status, that is partially unproductive from a metastatic point of view.

3. The third category is that of cells that have reached the metastatic site and launch an efficient proliferation process, that allows the cells to grow in number and to invade the metastatic site. These cells can be either from the bloodstream, or dormant cells, that have been locked in the G0 phase for a certain amount of time.

The phenomenon of “dormancy” of cells situated in metastatic sites has been studied in patients with breast cancer, where CTCs have been identified if 22

years distance from the radical intervention (20). However, the clinical implications of this event are still unclear. Moreover, these sites with dormant tumor cells have been found to be capable of releasing CTCs in the bloodstream, which is why it is important to identify and characterize these cells in the patient's circulation (21).

The utility of identifying and counting the CTCs

Circulating tumor cells may be identified and counted in the patient's blood, with methods that have seen great improvements over the last couple of decades. The utility of examining CTCs in rectal cancer patients may be seen from several points of view:

1. as a screening instrument
2. for diagnostics
3. as predictive factors for orienting the treatment
4. as prognostic factors
5. for guiding and assessing the treatment the treatment
6. as a follow-up tool.

1. CTCs could become primary or complimentary identification markers for rectal cancer, with the possibility of detecting tumor cells that are in the patient's bloodstream.

Studies from 2008 on breast cancer patients (22) and from 2012 on pancreatic cancer (23) support the idea that tumor cells enter the circulation even before the formation of the main tumor, thus concluding that the identification of CTCs in peripheral blood may be used for screening purposes.

2. Liquid biopsy is a popular subject in recent years. CTCs represent an important source of information in advanced neoplasia, in which they are more abundant in blood. However, the main goals are to identify them when they are less abundant in the patient's bloodstream, in early-stage neoplasia (which hinders them from being an adequate screening tool now) and to study them in their own tumor microenvironment (which may be solved by examining the heterotypical clusters of CTCs (24).

3. Prediction of the response to treatment for breast cancer has been studied in a phase III clinical trial – the SWOG S0500 trial, that was based on evaluating the number of CTCs at the beginning of the treatment and at 21 days after commencing chemotherapy; it aimed to observe the opportuneness of changing the line of chemotherapy after 21 days of chemotherapy based on the variation of CTCs. The trial demonstrates that a large number of cells at the beginning and at 21 days is a negative prognostic factor for disease free survival and overall survival. All in all, no clinical predictive utility of CTCs in adjuvant therapy was demonstrated through this trial (25).

However, this domain is promising and could show of great utility in locally advanced rectal cancer patients that must receive neoadjuvant therapy and develop metastases during this period of at least 12 weeks between diagnosis and the surgical sequence. CTC dosage during neoadjuvant therapy may prove to be of interest in this eventuality. No studies can be found on this subject now in literature.

4. An accepted and validated clinical usage of the CTCs is the relationship between the number of CTCs at the beginning of the treatment and the overall and disease-free survival. Thus, it has been

demonstrated that a number greater than 5 cells per 7.5 mL of peripheral blood is correlated with a worse survival (11). Moreover, this important aspect has been included, for breast cancer for the time being, in the last TNM classification (8th edition-2017): CTCs present in blood classify the disease as cM0(i+) (26).

This aspect has been initially studied in patients with breast cancer (27), but afterwards other types of cancer have been studied; in colorectal cancer, the cut-off value for CTC number per 7.5 mL of blood is 3, which is significant both for overall, as well as disease free survival (28).

5. The term of liquid biopsy has been widely discussed in the past few years and is a significant step forward for oncology. CTCs may prove to be an important marker both to be taken into consideration within the multidisciplinary team to decide upon the treatment, and for obtaining information about the tumor cell's phenotype and using this information to decide upon the elected treatment by each healthcare professional in part (29).

6. CTCs may be a precocious marker for recurrence or metastatic disease in rectal neoplasia, which is why a sensitive and accessible, cheap identification would be an important follow up tool.

All in all, CTCs are useful in all phases of the neoplastic disease, from screening to follow up. Nevertheless, their usage is subject to the refinement of identification and count methods. This domain is under development, but more trials are necessary to find and apply utilities of this resource in cancer treatment.

Methods of identification of CTCs

Because they are rare cells in the circulation, these cells' separation from leukocytes, red blood cells and other circulating cells is necessary. There are multiple methods of identifying these cells in the patient's bloodstream. A classification of these methods taking into consideration the modality used for selection divides them into (30, 31):

1. Affinity-based evaluation
2. Non-affinity-based evaluation (based on physical properties)
3. Molecular techniques of evaluation.

1. Affinity-based techniques are the most widely used modalities of evaluation of CTCs. These techniques are based on ligation to different antigens expressed by tumor cells, that differentiate them from other cells in the bloodstream. One of these molecules is EpCAM (Epithelial Cell Adhesion Molecule), that is expressed by tumor cells originating in epithelial tissue but is absent from other cells in the bloodstream. Thus, identification and ligation of this glycoprotein permits the selection of the targeted cells.

CellSearch is the most utilized method and is considered gold standard for the identification of CTCs. It is the only method approved by the US FDA for identifying and counting CTCs in breast, prostate and colorectal cancer. This method is based on ligation of EpCAM by iron-fluid nanoparticles and attachment of these functionalized cells in a magnetic field. This platform has been validated through multiple studies (30).

Other methods include Mag Sweeper (an automatic immunomagnetic separation technology), CTC-Chip (a chip that uses functionalized micro posts with anti-EpCAM antibodies), GEDI (geometrically

enhanced differential immunocapture). More recently, there have been described technologies that combine affinity-based methods with other physical techniques, thus emerging: Nano-Velcro (a device with a patterned silicon nanowire substrate coated with anti-EpCAM antibodies), Graphene Oxide Nanosheets with EpCAM antibodies, Immuno-microbubbles (perfluorocarbon gas filled microbubbles conjugated with anti-EpCAM antibodies) and GILUPI Cell Collector (a functionalized medical wire that detects CTCs in circulation, being inserted for 30 minutes in a peripheral vein) (30).

The disadvantages posted by these methods are the fact that tumor cells may present phenotypic variations, which may impede their detection by affinity alone, with less cells identified. This setback can be addressed by identifying and ligation of more than one type of CTC receptor.

2. These disadvantages led to the development of other methods of identifying and counting CTCs: methods based on size and electrical properties of CTCs. This is because tumor cells differ from other blood cells by size, density and polarity, alongside the molecules expressed on their surface.

The simplest, but the least effective method is centrifugation, which uses the cells' density to separate them from other blood components. Through centrifugation, CTCs are separated, along other nucleated cells in the blood, thus being identified afterwards by microscopic examination.

Based on the larger dimension of CTCs, compared to other cells in the blood, micro-filtering may be used, alone or in combination with other affinity-based or non-affinity-based methods. The filtrating material may be obtained through different modalities.

There are other methods to separate CTCs, such as microfluidics or Nano roughened surfaces, but these are still in the testing stage to evaluate their efficiency.

Dielectrophoresis is toe modality of separating CTCs in an electrical field. This technique has been patented by Herbert Pohl in 1950 and was observed as a modality of moving particles using their volume and form. Several studies have used dielectrophoresis in separating CTCs for studying them (31).

All in all, we can see that the methods are somewhat complimentary, and a method that combines them would be the most preferred, provided that is cost-efficient as well. GEDI (geometrically enhanced differential immunocapture) has been proven by Gleghorn to do this but has so far been used only in prostate cancer (32).

CONCLUSIONS

The emergence of the subject of CTCs has been, throughout history, a tough one, because in 1869, when they were first described, the medical world was not evolved enough to see the advantages and begin research; only after more than a century were CTCs seen as a domain of great potential.

We can conclude that the subject of CTCs is an emerging one, of great possibilities, with utilities that are reachable through research and refinement of the isolation techniques. The fact that CTCs are useful both in the field of oncology and in surgery is one more argument in favor of the studies and extensive research that are being put into this field.

COMPUTERIZED CALCULATION OF BREAST DENSITY: OUR EXPERIENCE FROM ARCADIA MEDICAL IMAGING CENTER (Abstract): The **aim** of this study was to implement a spatial fuzzy C-means algorithm for image segmentation and breast tissue density quantification and compare it with BI-RADS breast density classes determined by radiologists. **Material and methods**: The analysis was based on 206 mammograms performed in 111 women with various breast abnormalities. Digitized mammographic films were independently double read by radiologists certified in breast diagnosis, followed by consensus with arbitration agreement (radiological ground truth). Reporting was done using the BI-RADS mammography lexicon. Using an algorithm based on a combination of spatial fuzzy C-means clustering and binary thresholding, percent mammographic density was computed in digitized mammograms. The BI-RADS breast density readings were compared with percent breast density measurements determined by computer algorithm. **Results**: The algorithm was found to match the BI-RADS density classification in 90% of the cases, with an excellent agreement ($\kappa = 0.88$) between the radiological ground truth versus the algorithm breast tissue density estimates. **Conclusions**: Our study proposed an algorithm that can be applied both to digitized and digital mammograms, which proved to be effective in breast density estimates. The method can accurately determine the percentage density removing the human observer variability. The proposed method showed an excellent agreement with radiological ground truth. **Keywords:** MAMMOGRAPHIC DENSITY, SPATIAL FUZZY C-MEANS, BREAST SEGMENTATION, BINARY MASKS

Mammographic density is a risk factor for breast cancer, and it has been shown that women with high mammographic density have four to five-fold increased risk of developing breast cancer (1). Assessment of breast density may be carried out using qualitative or quantitative estimates. The most widely used clinical density estimate is the qualitative evaluation based on the Breast Imaging Reporting and Data System (BI-RADS) classes developed by the American College of Radiology (ACR) (2). However, this classification scheme is still limited by its considerable intra- and inter-reader variability.

As an alternative to qualitative evaluation, different quantitative approaches have been developed. A quantitative method for measuring breast density is supposed to be simple, accurate, reproducible, and ready to be implemented with a minimum level of operator dependency. In the assessment of

breast density from mammograms, the breast is usually segmented into distinct regions (3). There have been various approaches proposed to the task of segmenting the breast profile region in mammograms. Some of these have focused on using threshold (4), fuzzy C-means approaches (5), Gaussian mixture models (6) and statistical methods (7).

In this paper, we investigated the feasibility of quantifying breast density with an automatic approach, employing spatial fuzzy C-means (SFCM) clustering segmentation and binary thresholding.

MATERIAL AND METHODS

The mammographic records of 117 consecutive women (mean age, 56 years) who underwent diagnostic mammography at our facility was included in the present study. Standard cranio caudal view (CC) and medio lateral oblique (MLO) image projections of each breast were obtained. Subjects who had very poor quality mammograms were excluded. A data set of 95 cases of two-view bilateral mammograms and 16 two- view unilateral examinations (patients who had undergone mastectomy) was used in this study. No informed consent was required, as patient identification information was removed. This research protocol has been conducted according to the ethical guidelines and principles of the Declaration of Helsinki.

All mammographic examinations were performed by using a Senographe DMR unit (GE Healthcare, Milwaukee, Wisconsin, USA) along with a screen-film technique (Kodak Min-RS Film; Carestream Health Medical Imaging, Rochester, NY). All film-screen mammograms were digitized by using Diagnostic PRO Advantage film digitizer (VIDAR Systems, Herndon, Virginia, USA) with a dedicated software that convert images in Digital Imaging and Communications in Medicine (DICOM) format at a high resolution (570 dpi) of 44.5 microns and a 12-bit grayscale imaging output.

Image segmentation. To further process the digitized film mammograms we used public domain image-processing software, FIJI/ Image J (8), with a SFCM algorithm implemented as a plug-in.

The first step of our approach consisted in breast image segmentation. The SFCM method relies on classifying pixels into distinct regions containing a group of connected pixels (cluster) with similar properties within each group (9).

First, let $X = (x_1(1\ ), x_1 2, \ldots, x_1 N\ )$ be an image with N pixels to be partitioned into c clusters, where x_j is an image pixel. The identification of clusters in the image depends on a cost function that exploits the feature-based similarities between pixels, defined as:

$$J = \sum_{j=1}^{N}\sum_{i=1}^{c} u_{ij}^{m} \|x_j - v_i\|^2 ,$$

where u_{ij} is the membership function of pixel x_j in the ith cluster, v_i is the ith cluster center, $\|.\|$ is the Euclidean distance, and m is a constant which determines the amount of fuzziness of the resulting classification. The SFCM algorithm takes into account the local spatial relationship between adjacent pixels by introducing the spatial information into the membership function for clustering. SFCM algorithm can be summarized as follows: a set of integers as a parameter of the number of clusters to be allocated to the algorithm, c $=\{3, 4, 5, 6\}$.

A weighting exponent (fuzzifier) m $=\{1.1, 2.5\}$, and a parameter p that deter-

mines the influence of the weights, p ∈ [1…∞] . The spatial function it is defined as the probability that pixel x_j belongs to i^{th} clustering:

$$h_{ij} = \sum_{k \in NB_{(xj)}} u_{ik} \quad ,$$

where $NB_{(xj)}$ is a square window centered on pixel x_j in the spatial domain. The spatial function is incorporated into membership function as follows:

$$u_{ij}^{*} = \frac{u_{ij}^{p} h_{ij}^{q}}{\sum_{k=1}^{c} u_{kj}^{p} h_{kj}^{q}} ,$$

where p and q are parameters to control the relative importance of both functions, as described in detail elsewhere (10).

The SFCM method generated images of dense, adipose and whole breast tissue each one representing a cluster whose membership function u_{ij}^{*} indicates that the pixels are toward that cluster (fig. 1).

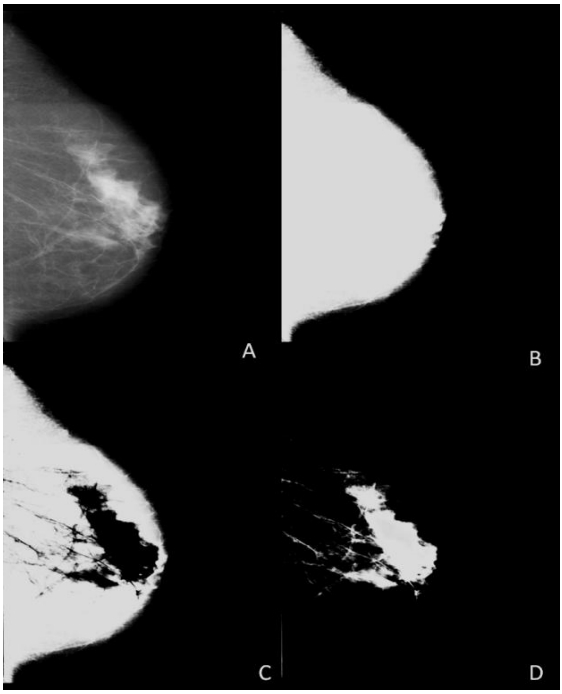

Fig.1. Steps for the segmentation of the fibro glandular breast tissue using SFCM: (A) Original digitized mammogram; (B) Segmented image of the whole breast; (C) Segmented image of the fatty regions; (D) Segmented image of the fibro glandular regions.

Estimation of mammographic density. For breast tissue density quantification only the CC projections were used, as it has been previously reported that density estimates from CC and MLO views showed very strong correlation (11). Images corresponding to dense and whole breast region were transformed into binary images using the isodata thresholding algorithm implemented in Image J. The method separates the image into breast tissue and background by automatically choosing a global threshold

that is equidistant from the average intensity of pixels below and above it:

$$Threshold = \frac{(average\ background + average\ tissue)}{2}.$$

The area-based measurements of mammographic density were computed by recording the number of pixels that lie within the defined region (fig. 2). The percent mammographic density (PD) was then calculated as the ratio of dense area to the total area of the breast multiplied by 100.

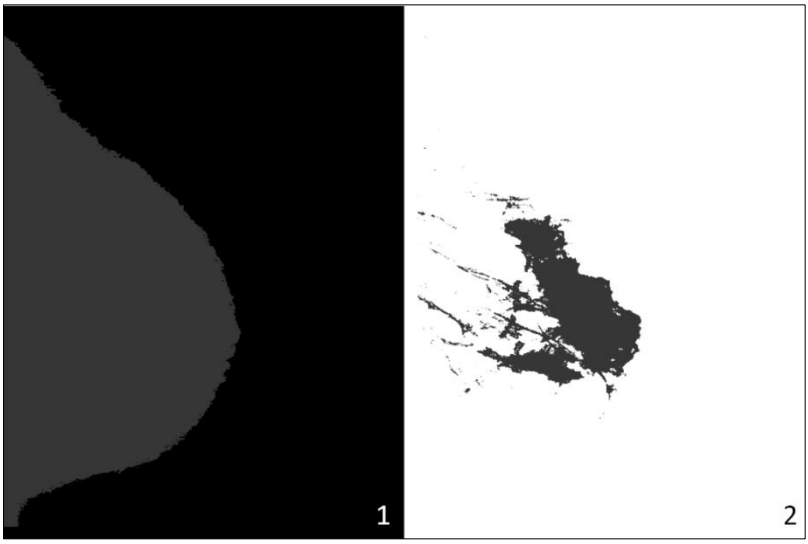

Fig. 2. The whole breast area delineation in CC views (1);
The fibro glandular area delineation in CC view (2)

Visual interpretation of digitized mammograms.

Each mammogram was initially independently reviewed by two trained breast imaging radiologists using the corresponding digitized screen-film mammograms. The CC and MLO views were displayed side-by-side on dedicated image displays (Totoku, Electric Co Ltd, Japan). The observers evaluated each case according to the BI-RADS mammography lexicon published by the ACR (2). After scoring the mammographic breast density in one of the four quantitative BI-RADS categories, the observers assessed the presence of associated findings such as masses, architectural distortion, focal asymmetry and calcifications. All lesions were described by using the terminology of the fourth edition of the BI-RADS lexicon and assigned to a final BI-RADS category. For cases with discordant results, a consensus reading with arbitration by a third expert radiologist was carried out, and the observers were asked to make the final assessment considered the ground truth.

Statistics. In order to facilitate convenient evaluation of the interobserver agreement, data readouts from the left and right breasts were pooled. Weighted kappa values were calculated to assess the level of agreement between observers. The interpretation of the kappa values was based on the criteria proposed by Landis and Koch (12): 0.20 or less indicated poor agreement; 0.21–0.40, fair agreement; 0.41-0.60, moderate

agreement; 0.61–0.80, substantial agreement; and 0.81–1.00, excellent agreement. The Wilcoxon signed-rank test was used for comparisons between the right and left breast. The Pearson's correlation coefficient was used to test the association between the PD area and patients age. All P values less than 0.05 were interpreted as statistically significant. All statistical analyses were performed by using *MEDCALC* software, *version 12.5.0* **(**Mariakerke**,** Belgium**).**

RESULTS

Visual interpretation of digitized mammograms.

Of 206 breasts analyzed, 95 (46%) were classified as fatty, 62 (30%) as scattered fibro glandular densities, 29 (14%) as heterogeneously dense, and 20 (10%) as extremely dense. There was a total of 53 (26%) breast masses, of which 11 (5%) histologically proved malignant, and 42 (21%) presumed benign. Calcifications within breast tissue were found in 88 (43%) breasts, of which 6 (3%) were associated with malignancy. Architectural distortion and focal asymmetric densities were found in 3 (1%) and 26 (13%) breasts, respectively. A total of 69 breasts were assigned to BI-RADS class 1, 79 to class 2, 39 to class 3, seven to class 4, and nine to class 5. Interobserver agreement at the first reading varied from substantial ($\kappa = 0.67$ for breast composition, $\kappa = 0.75$ for masses, $\kappa = 0.65$ for calcifications and $\kappa = 0.62$ for BI-RADS class) to fair ($\kappa = 0.36$ for focal asymmetry and $\kappa = 0.33$, for architectural distortion).

Breast density evaluation. The measured mammographic density was 36 ± 20% for the right breast and 34 ± 20% for the left breast (P=0.45). Breast density showed a statistically significant inverse relationship with age (Pearson product-moment correlation coefficient, $r = -0.32$, $P<0.001$). Based on the PD values (<25%, 25%–50%, 51%–75%, and ≥75%), each breast was assigned to the corresponding BI-RADS density class. When compared with the results of the consensus reading, overestimation occurred in 6% of the cases and underestimation in 4%. Agreement between the consensus reading versus algorithm PD estimates was excellent, with weighted kappa values of 0.88 (tab. I).

TABLE I

Visual classification and the software analysis of the breast composition categories (N=206 breasts).

	Consensus reading	**Algorithm estimates**	**Observer 1**	**Observer 2**
Almost entirely fat	95 (46%)	94 (46%)	77 (37%)	110 (53%)
Scattered fibro glandular densities	62 (30%)	63 (31%)	73 (36%)	49 (24%)
Heterogeneously dense	29 (14%)	29 (14%)	36 (17%)	25 (12%)
Extremely dense	20 (10%)	20 (10%)	20 (10%)	22 (11%)
Correct classification	-	186 (90%)	175 (85%)	169 (82%)
Classification overestimated	-	12 (6%)	27 (13%)	14 (7%)
Classification underestimated	-	8 (4%)	4 (2%)	23 (11%)
Weighted kappa- κ	-	0.88	0.84	0.80

DISCUSSION

In this study we propose an automatic method for breast density estimates that is fast, accurate and easy to implement at minimal costs. We used open-source software, Fiji/Image J distribution, which can be downloaded for free. All of the image-processing algorithms used in this work are available as plug-in that can be tailored to user's specific needs. Using only open-source software, we have tried to make our results reproducible and therefore easy to replicate.

Quantitative analysis of mammographic density would provide an objective assessment of breast cancer risk (13, 14) associated with varying mammographic densities. The main advantages of the proposed method are the completely automated breast segmentation and automatic thresholding technique. The algorithm was found to be superior to single-observer visual assessments in breast density measurements, matching the ground truth density classification in 90% of the cases.

The method has its disadvantages, because it is more time consuming than the visual assessment and require digitized images, but can accurately determine the percentage density removing the human observer variability. Additionally, an important limitation is that the area measurement from the 2D projection image ignores the variations in breast thickness.

Regarding algorithm optimization, a model for breast compression and thickness should be implemented and multiple comparisons between different devices (mammography systems, film scanning systems) are required, so further work is needed to implement this algorithm in routine practice.

CONCLUSIONS

Our study proposed an algorithm which proved to be effective in breast image segmentation and density estimates, with potential impact on diagnostic performance. The method is more time consuming than visual assessment, but can accurately determine the percentage density removing human observer variability. The main advantages of the proposed method are completely automated breast segmentation and automatic thresholding technique. The algorithm was found to be superior to single-observer visual assessments in breast density measurements. The proposed method showed an excellent agreement with radiological ground truth.

ELASTIN-LIKE POLYPEPTIDE -COLLAGEN HYDROGELS

In order to minimize post-surgical infections and support wound healing, Anderson *et al.* studied the preparation of hydrogels with effective antibiotic release profile and better mechanical properties. The team prepared elastin-like polypeptide (ELP)-collagen composite hydrogels that showed a higher elastic modulus in comparison to the collagen hydrogels. The release behavior of the collagen and ELP-collagen hydrogels loaded with varying dosages of a doxycycline hyclate was characterized. Both types of hydrogels showed a gradual time dependent release of doxycycline over a period of 5 days. The ELP-collagen hydrogels had a slower doxycycline release compared to the collagen hydrogels. The released doxycycline was effective in a dose dependent manner against strains of *E. coli, P. aeruginosa, S. sanguinis* and MRSA. The study concluded that ELP-collagen hydrogels have improved mechanical properties, effective drug release and may be beneficial for tissue engineering applications and drug delivery (Anderson TR1, Marquart ME, Janorkar AV. Effective Release of a Broad Spectrum Antibiotic from Elastin-Like Polypeptide-Collagen Composite. *J Biomed Mater Res A*. 2014. doi: 10.1002/jbm.a.35219. [Epub ahead of print]).

GLAUCOMA EVOLUTION IN PATIENTS WITH DIABETES (Abstract): Glaucoma and diabetes are two chronic diseases with a long suspected pathogenic relationship. **Purpose**: Screening for glaucoma in patients with diabetes. **Material and methods**: A retrospective study on 92 eyes from 46 patients with primitive open angle glaucoma (POAG) (normal and hypertensive) and intraocular hypertension (OHT) receiving medication and / or surgery associated with diabetes mellitus (DM) (type I, type II, mixed) is presented. Participants were divided into two groups as following: 16 eyes with glaucoma and diabetic retinopathy changes (group1) and 76 eyes with glaucoma and without diabetic retinopathy changes (group 2). The following parameters were analysed: ocular pressure (Goldmann aplanotonometry), perimeter development (computerized perimetry) and fundus condition (absence, presence or progression of diabetic retinopathy). **Results**: In patients with glaucoma and diabetic retinopathy (8 patients) we found a mean difference between treated intraocular pressure (IOP) and IOP last untreated control of 4.95 mmHg; a depreciation of the MD by 4.18 dB and an average number of glaucoma medications used of 0.889 ± 1.054. Predominant changes in proliferative diabetic retinopathy were mild. In patients with glaucoma in the absence of diabetic retinopathy, the average difference between untreated IOP and IOP under treatment at the last check-up was 1.63 mmHg, the MD depreciation was by 0.65 dB and the average number of glaucoma medications used was 0.795 ± 0.978. **Conclusions**: No statistically significant differences in terms of initial and final pressure were found. No statistically significant differences in the evolution of changes in perimeter between the two groups were observed. The presence of non-proliferating diabetic retinopathy influenced (only marginally statistically) the glaucomatous disease progression. Large comparative prospective studies are needed for the long-term follow up. **Keywords**: POAG, DIABETES, PIO, MEAN DEVIATION, DIABETIC RETINOPATHY

Glaucoma and diabetes are two chronic diseases that affect the population for over 40 years, views on its relationship are considered pathogenic (1). Numerous studies have attempted to find an association between diabetes and primary open-angle glaucoma (POAG), some successfully, some not. MO Gordon and colleagues presented a study of 1637 subjects in 1999, which included a large number of risk factors including diabetes. The study concluded that 3.1% of the population does develop glaucoma, and that diabetes acts as a protective factor to decrease the probability of developing POAG (2). This early conclusion was in part due to a relatively small

number of people with diabetes excluding those with diabetic retinopathy changes. Several studies have tried and have failed to demonstrate an association between diabetes and glaucoma. In an article by Benkes (3) in 1967 suggested for the first time the relationship between glaucoma and diabetes, "diabetes occurs more frequently in those with POAG than in the population without glaucoma claiming, glaucoma is more prevalent in patients with diabetes than without". The Rotherham Study concluded, "newly diagnosed diabetes and high blood glucose levels are associated with elevated IOP and glaucoma with high pressure" (4). In a recently published article entitled "Diabetes - risk factor for glaucoma?", the authors showed that both diseases have a vascular component and retrobulbar blood flow abnormalities in retinal microcirculation were found in both diabetes and glaucoma (5). Our study objective was to follow the development of glaucoma specifically in patients with diabetes.

MATERIAL AND METHODS

We performed a retrospective study on 92 eyes from 46 patients recorded with normal or hypertensive POAG, an OHT treated with drugs and/or surgery both associated with diabetes (type I, II and mixed). All patients were selected from „Sf. Spiridon" University Hospital of Iasi between January 2009 – May 2012. The inclusion criteria were: normal or hypertensive glaucoma, OHT associated with diabetes. Patients with other types of glaucoma were excluded (pseudoexfoliation, pigment, cortisone, and primitive neovascular angle closure) as well as those without associated diabetes. Participants were divided into two groups as following: group 1 represented by patients with glaucoma and changes of diabetic retinopathy (DR) and group 2 patients with glaucoma and without DR.

All patients were monitored under the following parameters: the clearance pressure (with Goldmann applanotonometer), the perimetrical progression (by automated perimetry with Humphrey Field Analyzer II) and fundus change evaluated with the Volk lens 78D (absence, presence and progression of DR). It was also recorded the duration of glaucoma, diabetes and number of glaucoma medications used.

Diagnosis criteria for normal or hypertensive POAG were: age >35 years, normal IOP or >21mmHg without treatment, open angle gonioscopy, the presence of optic nerve damage (ratio c/d > 0.5), abnormal visual field (Humphrey Field Analyzer by perimetry) and normal or diffuse or localized defects in the retinal nerve fiber layer (optical Coherence tomography Cirrus HD-OCT Zeiss) (6).

Evaluations of the changes in diabetic retinopathy were performed with Volk lens and retinal photography with Fundus Camera Zeiss. Retinal changes in dilated pupils were monitored. The criteria for classification as DR changes (ETDRS) were the following: unchanged or absence of signs of DR, mild nonproliferative diabetic retinopathy (presence of only microaneurysms), moderate DR (microaneurysms, haemorrhages in 2-3 quadrants, venous dilatation and exudates), severe DR (microaneurysms, hemorrhages in all quadrants, dilated veins in 2-3 quadrants, exudates) and proliferative diabetic retinopathy (neovascularization disk and retina in different quadrants). It was considered progression of DR any new clinical item appearing on subsequent checks that led to their classification as severe nonproliferative or proliferative diabetic retinopathy (7). Sigma Plot was used for the statistical analysis of the results (student t test).

RESULTS

In our study all the 92 eyes from 46 patients met the eligibility criteria. The mean age was 62.87 ± 8.4 years (between 39 and 80 years old). Among patients with DM 36 had DM type II, 5 had DM type I and 5 with insulin-dependent DM type II. From all studied eyes, 72 eyes (78.26%) had POAG, 10 eyes (10.87%) had normal tension glaucoma (NTG) and 10 eyes (10.87%) OHT (fig.1). Regarding the changes in diabetic retinopathy, of the 8 patients, 5 had mild changes in diabetic retinopathy (15%), 3 had proliferative diabetic retinopathy (7%) and the rest (78%) did not show any change (fig.2).

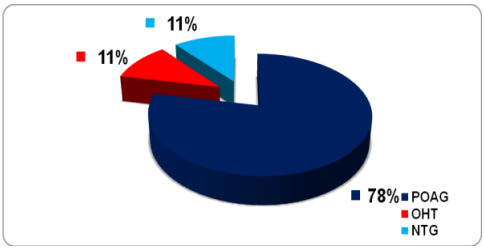

Fig. 1. Distribution of patients with glaucoma POAG = primitive open angle glaucoma, OHT = ocular hypertension, NTG = normal tension glaucoma

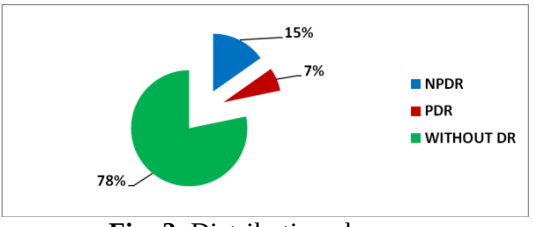

Fig. 2. Distribution changes of diabetic retinopathy

NPDR = diabetic retinopathy mild form, PDR = proliferative diabetic retinopathy, Without DR = no modification of diabetic retinopathy

The average duration in years of glaucoma in group 1 was 1.7 ± 1.16 (range 0-3) and 4.33 ± 4.602 (range 0-19) in group 2. No statistically significant differences were found between the two groups (P <0.05 for significant relevant statistics) (tab. I).

TABLE I

Statistical distribution of glaucoma

	group1	group2
Glaucoma duration (years)	1.7 ± 1.16	4.33 ± 4.602
	(0-3)	(0-19)
t student	(P=0.818)	

The average duration of diabetes in years was in group 1 with 9 ± 10.029 (range 0-26) and 4.59 ± 4.284 (range 0-17) in group 2, no statistically significant differences existed between the two groups (tab. II).

TABLE II

Statistical distribution diabetes

	group1	group2
Diabetes duration (years)	9 ± 10.029	4.59 ± 4.284
	(0-26)	(0-17)
t student	(P=0.081)	

The mean number of glaucoma medications used was similar in the two groups, respectively 0.889 ± 1.054 (range 0-3) in group 1 (glaucoma + DR) and 0.795 ± 0.978 (range 0-3) in group 2 (glaucoma without DR) as there were no statistically significant differences in student t-test between the two groups (tab. III). In group 1 the glaucoma and DR average difference between the initial untreated IOP and the final treated IOP at the last check-up was 4.9 mmHg. Patients whose IOP was less than 23 mmHg after one single medication did not require any further intervention to reduce the IOP (fig. 3).

In group 2 (glaucoma and without DR) we found a mean difference of 1.63 mmHg between the initial untreated IOP and final treated IOP at the last check-up. The initial pressure was also lower compared to the group 1. As a consequence the majority of cases did require a small number of drugs and only 2 cases with IOP >30 mmHg required three drugs to reduce pressure (fig. 4).

By comparing the mean IOP of the two groups using Student t test a p value of 0.062 was obtained. This value is however statistically insignificant since p <0.05 is considered statistically significant (fig. 5).

Analyzing the characteristic parameters of standard perimeters, particularly of Mean Deviation (MD) an impairment of the MD's of 4.18 dB was found in group 1 (glaucoma and DR) (fig. 6). In group 2 (glaucoma and without DR) a MD's depreciation of 0.65 db was found (fig. 7).

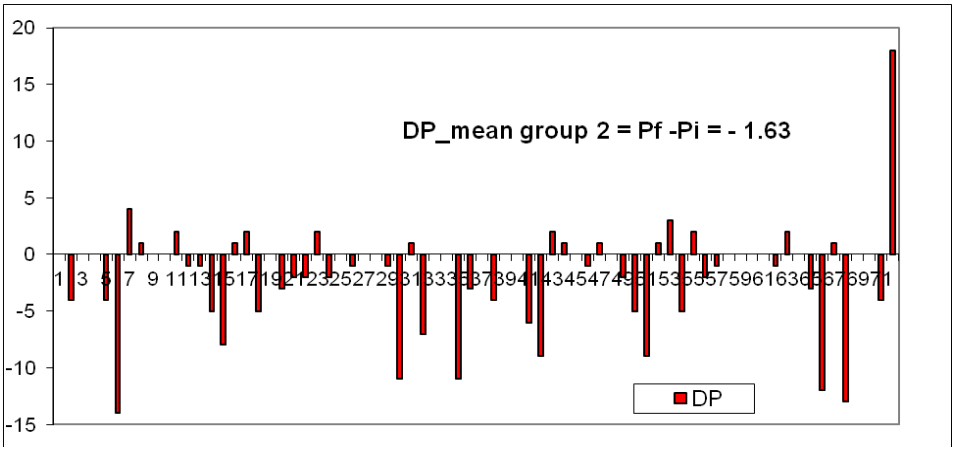

Fig. 4. Statistical description of the mean pressure difference outcomes in group 2
Pf = final pressure therapy, pi = initial pressure therapy,
DP_mean = average difference between the final and initial pressure

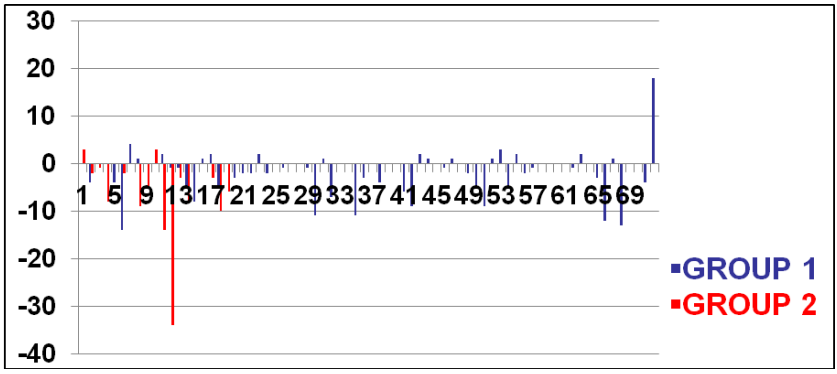

Fig. 5. Statistical significance average initial and final pressure between the two groups

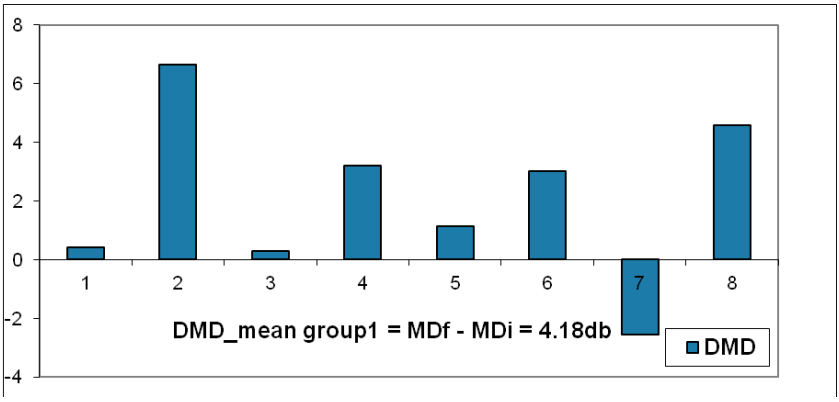

Fig. 6. Statistical description of the results - MD mean value group 1
MDf = mean deviation final, MDi = mean deviation initial from the first control

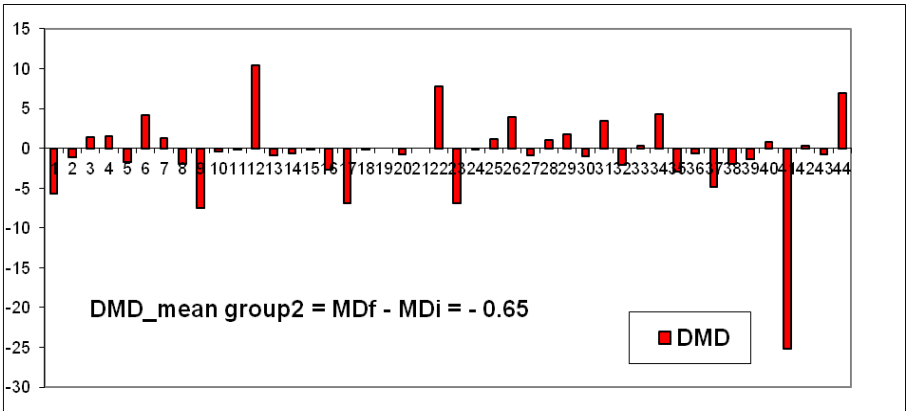

Fig. 7. Statistical description of the results - MD mean value group 2
MDf = mean deviation final, MDi = mean deviation initial from the first control

However when comparing the average MD of the two groups using Student t test a p-value = 0.044 was obtained which is a statistically significant value although only marginal ($p<0.05$ to be statistically significant) (fig.8). The statistical analysis of the data showed higher initial value of the IOP in the group 1 (glaucoma+DR), which required a greater number of drugs to reduce it, while long standing diabetes (0-28 years) correlated positively with the presence of diabetic retinopathy and the MD's important depreciation (4.18 db) vs group 2 (glaucoma and without modifications RD). All these results reveal the statistically significant difference in terms of the average MD and confirm that this influenced the diabetic retinopathy (although marginally statistically) and the glaucomatous disease progression.

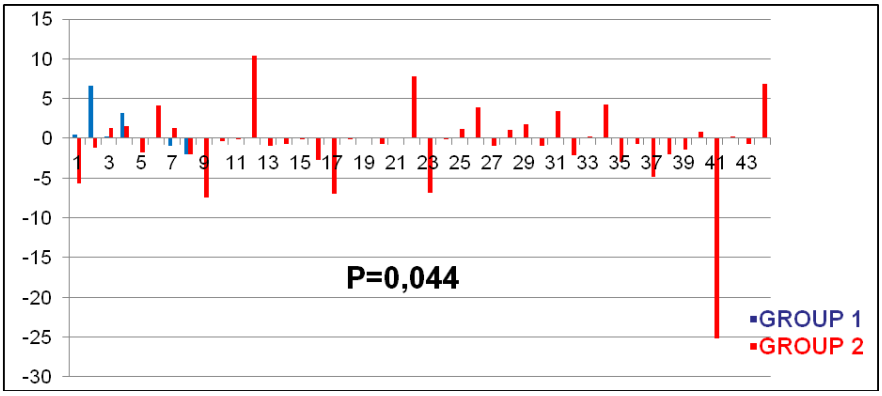

Fig. 8. Mean statistical significance initial and final MD between the two groups

DISCUSSION

Secondary conditions such as vascular degeneration related to diabetes cause some severe risks to the eye such as diabetic retinopathy, crystalline opacities, increased intraocular pressure, rubeosis iridis and open-angle glaucoma. Furthermore IOP has a role in the development of diabetic reti-

nopathy and influences the development progression of glaucoma. Eyes with proliferative diabetic retinopathy had IOP lower than those with non-proliferative diabetic retinopathy. Increased IOP may protect by delaying DR changes. The statement " Increased IOP may protect by delaying DR changes" is controversial; low IOP associated with worsening diabetes as a logical consequence of the Starling law (on the balance between the intravascular and extravascular fluid transfer) (8). Many studies on patients with glaucoma and diabetes are clinical and retrospective and population-based. However obtaining sufficient information from any systematic retrospective study is difficult. A large number of studies have been conducted over time, some have found an association between glaucoma and diabetes, others have shown the opposite (2), or failed (Baltimore Eye Survey, The Rotherham Study) (9, 10, 11). The controversial Ocular Hypertension Treatment Study conducted in 2002 (2) does not find a correlation between the two disorders further supporting that diabetes is a protective factor for glaucoma (glaucoma develops only 3.1% of those with diabetes). It should be noted that compared to our study they did not include patients with diabetic retinopathy, which could change the results of the study. The 22% of those included in our study with diabetic retinopathy, glaucoma influenced the evolution (depreciation MD's with 4.91 dB 0.65 dB in group 1 vs group 2) even if marginal ($p = 0.044$, $p < 0.05$ to be statistically significant). The age group 1 diabetes in years (range 0 - 29 years old) also may play a role in the changes of diabetic retinopathy and glaucomatous disease evolution. Of those that have found an association between the two disorders are groups for which their group resembles the selection of cases and results of our study (10, 11, 12). Barbara Klein and colleagues published in BJO 1997 a prospective study at 10-year in which she examined the incidence of glaucoma in patients with DM. In her study she found that glaucoma is more prevalent in those with long-term diabetes and treated with insulin (12). Los Angeles Latino Eyes Study, a population-based study that included patients with glaucoma DM type II and demonstrated that this DM type II and its long-evolution (duration > 15 years) had a higher prevalence (40%) of developing glaucoma ($p<0.0001$) (13). The difference from our study is that it included only patients with type II diabetes ($a < 30$ years treated with oral agents or by diet) while diagnosis of glaucoma was based on the optic nerve appearance, regardless of the IOP. We found that in our group, most participants had DM type II (78%), a small percentage being with DM type I and mixed. Similar Blue Mountain Study, study of the population range that includes 40% black participants, argues that there is a significant and consistent association between diabetes and glaucoma (14).

Despite all the contradictions in the literature, our study shows similar results to recent studies, however we believe a prospective, general study on a larger number of patients and with a longer follow-up period should be conducted.

CONCLUSIONS

This study demonstrated an association and support that diabetes influences the evolution of the open-angle glaucoma in our patients. We have also found statistically significant differences in the evolution perimeter changes (Mean Deviation) between the two groups ($p = 0.044$). In group

1 represented by patients with glaucoma and diabetic retinopathy depreciation, MD was 4.91 dB (glaucoma progression) compared with group 2 (glaucoma + without RD) which was only 0.65, this allowed us to say that the presence of diabetic retinopathy changes even if statistically marginal influenced by the evolution of glaucomatous disease. Regarding the evolution of initial and final IOP no statistically significant differences between the two groups were found. This study has however several limitations: it is a retrospective study, the number of patients is small, high group heterogeneity (smaller number of patients with glaucoma and RD) and short duration of follow-up. Future prospective studies containing comparative larger batches of patients are necessary for a more accurate idea of the influences of the two diseases.

SUPRAVENTRICULAR ARRHYTHMIAS IN PATIENTS WITH ESSENTIAL ARTERIAL HYPERTENSION - CLINICAL-EVOLUTIVE CORRELATIONS. (Abstract): **Aim of the study**: The analysis of supraventricular rhythm disorders encountered in hypertensive patients and the establishment of correlations with other associated risk factors, duration of hypertension, the evolution and prognosis. **Material and methods**: The study included a group of 110 patients , 80 men and 30 women, aged between 40 and 85, admitted in the 1st Cardiology Clinic during 2010-2013, diagnosed with essential arterial hypertension second and third degree. For the detection of arrhythmic events surface 12-lead ECG and 24-hour Holter monitoring were used. **Results and discussion**: supraventricular arrhythmias encountered in the patients of the group were: ESA (mostly isolated, but also doublets, atrial bigeminy), atrial fibrillation, atrial flutter, sinus tachycardia, sinus bradycardia. Some arrhythmias may be an expression of the excessive activation of the sympathetic nervous system or on the contrary, vagal predominance, (ex. sinus bradycardia). Part of the arrhythmias occurring in hypertensive patients are hypertensive heart disease expressions, others are due to associated risk factors (smoking, alcohol) and even medication administered. In some cases, rhythm disturbances disappear with the normalization of the blood pressure; however, most of the times, the specific combination of anti-arrhythmic medication with antihypertensive medication is required. **Conclusions**: supraventricular arrhythmias are frequently found in hypertensive patients, especially in those with long term, uncontrolled hypertension, with impact on the evolution, prognosis and therapeutic management. **Keywords**: HYPERTENSION, SUPRAVENTRICULAR ARRYTHMIAS.

Essential high blood pressure (HBP) continues to be an extremely important health problem, on the one hand being a major risk factor for ischemic heart disease, and on the other, due to the complications that affect the targeted organs (1, 2, 3). One of the manifestations of hypertensive heart disease are the arrhythmias (supraventricular as well as ventricular) which, when they appear, alter the course and prognosis of the hypertensive patient and at the same time require treatment particularities (4, 5, 6, 8). Left ventricular hypertrophy caused by uncontrolled arterial hypertension is considered a major risk factor for the development of subsequent arrhythmias (4, 5, 7, 8).

Aim of the study**:** The analysis of the supraventricular rhythm disorders encoun-

tered in hypertensive patients and the establishing of correlations with associated risk factors, duration of hypertension, and the development and prognosis.

MATERIAL AND METHODS

The study included a group of 110 patients, 80 (72.72%) men and 30 (27.27%) women, with ages between 40 and 85, hospitalized in the 1st Clinic Cardiology during 2010-2013, with a diagnosis of essential hypertension of the second and third degree. The diagnosis of arterial hypertension was based on the classical criteria: blood pressure (BP) values above 140/90 mmHg at rest, in the absence of antihypertensive drugs on repeated measurements. All the patients were asked about the duration of hypertension, hypertension-related symptoms, and treatments followed up to the time of admission.

All the patients underwent a complete functional balance of hypertension which consisted of:

- Complete clinical examination of the cardiovascular system: auscultation of the heart, carotid arteries, abdominal aorta and renal arteries;
- Assessment of associated risk factors (smoking, diabetes, obesity, alcohol consumption, stress);
- Measuring the BP in supine and standing position on both arms;
- Complete 12 lead ECG;
- 2D echocardiogram, M mode and Doppler for the assessment of LV systolic and diastolic function and any murmurs;
- Chest X-ray - for the assessment of cardiomegaly and pulmonary stasis;
- Fundus;
- Renal function and serum electrolytes;
- Urinalysis examination;
- Complete lipid profile, blood glucose and uric acid;
- In some patients, BP monitoring 24 hours (ABPM) and 24-hour Holter monitoring for arrhythmias was used ambulatory.

The functional balance was completed in some cases with a minimum etiology balance to rule out a possible cause of secondary hypertension. In the detection of arrhythmias surface electrocardiogram and/or 24-hour Holter monitoring was used and 24 -hour Holter monitoring was performed on 82 patients (74.5 %).

RESULTS AND DISCUSSION

A group of 110 patients has been studied, 80 men and 30 women, with ages between 40 and 85, with the essential hypertension diagnosis.

Depending on the BP values the lot division was as follows:

- Hypertension 1st degree - 20 (18.18%) patients, 12 men, 8 women.
- Hypertension 2nd degree - 40 (36.36%) patients, 30 men, 10 women.
- Hypertension 3rd degree - 50 (45.45%) patients, 38 men, 12 women.

The risk factors analysis in the studied group has shown the following:

- Smoking - 60 (54.54%) patients, 50 men, 10 women.
- Obesity, varying degrees 1-4: 75 (68.18%) patients, 25men, 50 women.
- Dyslipidemia - 85 (77.27%) patients, 75 men, 10 women.
- Diabetes type 2 - 30 (27.27%) patients, 20 men, 10 women.
- Diabetes type 1 - 1 case.
- Alcohol - 70 (63.63%) patients, 65 men, 5 women.
- Stress - 31 (28.18%) patients, 20 men, 11 women.
- In most cases, risk factors have been associated.

Supraventricular arrhythmias (detected on surface ECG or by 24-hour Holter moni-

toring) encountered in patients of the group were:

- Atrial extrasystole - 45 cases (40.9%) (26 men, 19 women) - mostly isolated, but also doublets, atrial bigeminy;
- Atrial fibrillation (AF) - 35 cases (31.81%) (23 men, 12 women);
- Atrial flutter - 5 cases (4.5%) (4 men, 1 woman);
- Sinus tachycardia -18 cases (16.36%) (10 men, 8 women);
- Sinus bradycardia - 13 cases (11.81 %) (7 men, 6 women);

Regarding the medication that the patients have received, it was found that:

- 44 (40%) patients received a diuretic (indapamide) associated with angiotensin converting enzyme inhibitors (enalapril, quinapril, perindopril, ramipril);
- 34 (30.9%) patients received a diuretic (indapamide) associated with angiotensin converting enzyme inhibitors (enalapril, perindopril, ramipril), and a beta-blocker (metoprolol or nebivolol);
- 10 (9.09%) patients received a diuretic (indapamide) associated with angiotensin converting enzyme inhibitors (enalapril, perindopril, ramipril) and anticalcic (amlodipine or slow release nifedipine);
- 15 (13.6%) patients received ARBs (telmisartan, candesartan) associated with diuretic (indapamide);
- 7 (6.36%) patients received a quadruple combination: diuretic, ACE inhibitor, beta blocker, calcium channel blocker);

Of the entire group, digoxin was used for 10 (9.09%) patients as antiarrhythmic; for 24 (21.81%) patients, propafenone was used for the control of atrial and/or ventricular extrasystolic arrhythmias.

Most of the patients in the group have received antiplatelet therapy (aspirin or clopidogrel), and, for 25 (22.72%) of the patients, oral anticoagulants were considered necessary (the patients with atrial fibrillation and dilated left atrium seen at echocardiography).

In the group of patients with atrial extrasystole, the majority were men, smoking and consuming alcohol. A correlation between the duration of hypertension and the presence of atrial extrasystole could not be made, but atrial extrasystole presence could be correlated with the systolic blood pressure value. Thus, patients who had values above 190 mmHg SBP had a greater incidence of atrial extrasystole. A positive correlation between the size of the left atrium and the presence of atrial arrhythmias has also been found.

In patients with AF the following findings were made:

- AF was more frequent in male hypertensive patients who associated as risk factors smoking and alcohol consumption;
- AF appearance correlated with the duration of hypertension (over 5 years), with the presence of left ventricular hypertrophy changes on the surface ECG and on the echocardiogram, and also with the size LA (at echocardiography);
- All patients in this group had varying degrees of left ventricular hypertrophy and LA dilated (over 50/50 mm);
- In 12 (10.9%) patients from this group the presence (both as ultrasound and clinical) of aortic and mitral regurgitation was highlighted.

In patients with atrial flutter, four patients were male and one, female. All male patients had uncontrolled hypertension until the time of admission and were also drinkers (declarative and positive markers). Female patients were also old, hypertensive, with BP neglected and consuming alcohol.

From the group of patients with AF and atrial flutter, 15 (13.6%) patients, 12 men, and 3 women, presented the clinical features of angina pectoris associated with the

presence of ischemic electrocardiographic changes. In all these patients were objectified elevated serum cholesterol, triglycerides and LDL cholesterol, dyslipidemia being an additional risk factor for ischemic heart disease.

From our group, 18 (16.36%) patients (10 men, 8 women) had constant sinus tachycardia, defined as a heart rate above 100/min in sinus rhythm. Of these, 4 patients (3 men, 1 woman) were diabetic, one under insulin therapy, and 5 were previously treated with calcium channel blocker (nifedipine or amlodipine).

Sinus bradycardia was encountered in 13 (11.8%) cases (7 men, 6 women), heart rate was between 48-55/minute. In 5 cases drug etiology was taken into account; patients were previously treated with beta-blocker.

CONCLUSIONS

The presence of supraventricular rhythm disorders in hypertensive patients has the following implications:

- Some arrhythmias may be an expression of an excessive sympathetic nervous system activation or, on the contrary, of vagal predominance, if sinus bradycardia;
- A part of arrhythmias occurring in hypertensive patients are hypertensive cardiomyopathy expression (following a sustained, uncontrolled hypertension);
- A large percentage of these arrhythmias are due to associated risk factors (smoking, alcohol) and even medication management (e.g. frequent sinus tachycardia in patients who received treatment with the dihydropyridine group anticalcic or sinus bradycardia more frequently in those receiving beta-blockers);
- In some situations rhythm disturbances disappear with the normalization of the BP values, however, that often requires the specific combination of anti-arrhythmic medication with antihypertensive;
- Depending on the severity of certain arrhythmias (e.g. atrial fibrillation), they require combining anticoagulant and antiplatelet therapy.

PACT WITH THE DEVIL: ALEMTUZUMAB THERAPY, IMMUNE SUPPRESSION AND INFECTIOUS COMPLICATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA (Abstract). Infectious complications are an important cause of hospitalization in patients diagnosed with chronic lymphocytic leukemia. The pathogenesis of infection is complex, involving both disease-induced and treatment-related immune depression. During the last decade, the management of chronic lymphocytic leukemia (CLL) has been redefined by the approval of monoclonal antibody-based treatment, which resulted in improved therapeutic responses. Nonetheless, the profound lymphopenia induced by monoclonal agents was accompanied by increased incidence of infections caused by a new spectrum of opportunistic microorganisms. We report the case of a patient with hypercellular CLL who received Alemtuzumab as first line therapy and obtained a satisfactory therapeutic response, but developed subsequent atypical infectious complications. **Keywords:** CHRONIC LYMPHOCYTIC LEUKEMIA, ALEMTUZUMAB, IMMUNE SUPPRESSION, MYCOBACTERIUM TUBERCULOSIS, ATYPICAL INFECTION.

Infectious complications represent a significant cause of morbidity and mortality in patients diagnosed with chronic lymphocytic leukemia (CLL), infection-related mortality ranging between 30-50% (1).

The pathogenesis of infection is complex, involving both disease-induced and treatment- related immune depression. Immune depression determined by the natural course of the disease features hypogammaglobulinemia, T-cell subpopulations abnormalities, B-cell and neutrophil defects, as well as neutropenia through bone marrow involvement (2, 3). In addition to these preexisting abnormalities, specific therapy further increases the risk of infection by agent-specific effects on the immune system. Monoclonal antibodies represent a novel and innovative treatment approach in CLL, in combination with standard chemotherapy or in single-agent regimens. Alemtuzumab is a monoclonal antibody directed against CD 52, expressed on tumor cells, and normal B and T cells, and macrophages (4). Its introduction in CLL therapy has been linked to an in-

creased risk of viral infection, notably cytomegalovirus (CMV), opportunistic infections, prolonged lymphopenia and neutropenia, especially in pretreated patients or refractory disease (5,6). We report the case of a patient with hypercellular CLL who received Alemtuzumab as first line therapy with a satisfactory therapeutic response, but developed subsequent atypical infectious complications.

CASE REPORT

We present the case of a 41-year-old male patient with low socioeconomic status admitted to our hospital for general fatigue, night sweats and abdominal swelling experienced over the previous 3 months. Family and personal history were not significant. Physical examination revealed ECOG (Eastern Cooperative Oncology Group) performance status 2, splenomegaly 25 cm below the left costal margin, hepatomegaly 9 cm, and generalized adenopathy of 3 cm maximum diameter. The complete blood count revealed extreme hyperleukocytosis 934.000/mm^3, lymphocytes 919.000/mm^3, Hb 7.5 g/dl, and platelets 30.000/mm^3. Biochemical analysis showed elevated LDH, uric acid, and erythrocyte sedimentation rate, with the rest of the parameters within normal range. Pulmonary radiography was normal. Flow cytometry identified a lymphoid population with specific CLL phenotype, CD 38 negative. Risk assessment at diagnosis was based on hyperleukocytosis, large tumor mass, elevated LDH, CD 38 negativity, and absence of deletion 17 p. Due to the large circulating tumor mass, the patient was considered high risk. Alemtuzumab was started in standard regimen of weekly administration for 12 weeks, inducing a partial response: normalized lymphocyte count, persistent splenomegaly (24cm), hepatomegaly (8 cm), anemia and thrombocytopenia. In the eleventh week of treatment the patient developed a prolonged febrile syndrome. Alemtuzumab therapy was discontinued. The etiologic spectrum of febrile splenomegaly in this case included infection or CLL transformation to aggressive B-cell proliferation (Richter syndrome). Alemtuzumab therapy included the patient in the highest risk class for infection (grade 4 neutropenia (250/mm^3) and lymphopenia). Cytomegalovirus (CMV) infection was ruled out by successive PCR determinations. Hepatitis viruses were absent, and empirical antiviral therapy with acyclovir and valaciclovir was ineffective. Repeated blood cultures remained negative throughout the 2 months of persistent fever. Broad spectrum antibiotics were unsuccessful. Invasive hepatosplenic fungal disease was highly unlikely due to normal ultrasound appearance, normal liver function tests and unresponsiveness to empiric antifungal therapy. Serology for leishmaniosis was negative. We considered the possibility of a mycobacterial infection. Diagnostic splenectomy and hepatic biopsy were performed to rule out the probability of Richter syndrome. Histopathologic examination and tissue cultures certified the presence of Mycobacterium tuberculosis. The general health status of the patient declined immediately after splenectomy, with persistence of the febrile syndrome and cholestasis. The pulmonary radiography revealed features of disseminated miliary tuberculosis. The patient was referred to the pneumology department where standard tuberculostatic therapy was initiated (isoniazid, pyrazinamide, ethambutol, rifampicin) with prompt resolution of the febrile syndrome. Tuberculostatic treatment was continued for 9 months. The patient maintained the partial

therapeutic response for 2 years before disease recurrence through hyperleukocytosis and thrombocytopenia.

DISCUSSION

The major determinants of infection in CLL patients are tumor-associated immune deficiency and immunochemotherapy-related immunsuppression (3).

CLL specific immune deficiency features defects in humoral and cellular effector mechanisms, complement and neutrophil function. Hipogammaglobulinemia is a common finding (7).

Defects in cell-mediated immunity are mainly linked to T-cell dysfunction. Apart from purine analogue and alemtuzumab therapy, CD4+ and CD8+ T-cell defects are the direct effect of the malignant clone or cytokine secretion and include impaired intracellular signaling and cytoskeleton dysfunction reflected in modified motility, chemotaxis and deficient immune synapses (8, 9). Aberrant populations of suppressor T cells and Th2 responses have also been reported (3).

NK cell and monocyte dysfunction are being cited (10). Finally, neutrophyls exhibit migration and phagocytic defects, while neutropenia becomes more prominent in the late stages of the disease through extensive bone marrow infiltration (2,3,7).

During the last decade the management of CLL has been redefined by the approval of monoclonal antibody-based treatment, which resulted in improved therapeutic responses. Nonetheless, the profound lymphopenia induced by monoclonal agents was accompanied by a corresponding increase in the incidence of infections caused by a new spectrum of opportunistic microorganisms (5).

Alemtuzumab is a humanized monoclonal antibody directed against the CD52 antigen expressed on both normal and malignant B CLL lymphocytes, NK cells, monocytes, macrophages and eosynophils. It is currently indicated as first line therapy in high risk patients associating 17p deletion and as salvage therapy for fludarabine-resistant disease (5, 6). Its mechanism of action is both complement and cellular-dependent. Alemtuzumab treated patients develop profound and prolonged (up to a year) lymphopenia, resulting in the increasing incidence of low CD4 count-associated infections. The degree of therapy-induced immunosuppression is also determined by CLL stage, previous chemotherapy regimens and treatment response. The spectrum of Alemtuzumab-associated infections ranges from banal bacterial infections, CMV reactivation (10-25%), varicella zoster virus, parvovirus, herpes simplex infection, *Pneumocystis carinii* pneumonia to more atypical pathogens: *Cryptococcus, Histoplasma*, invasive fungal infections (*Aspergillus,Candida,Rhizopus, Fusarium), Rhodococcus* and mycobacterial infection (7). Mycobacterial infection in CLL patients has been documented less frequently, with an incidence of 88/10000 cases, and is correlated with steroid use and autoimmune phenomena (11).

We present a case of splenic mycobacterial infection developed 12 weeks after Alemtuzumab therapy, presenting as a prolonged febrile syndrome associating treatment-resistant splenomegaly. Alemtuzumab-associated immunosuppression raised a high suspicion of CMV or atypical infection but, as the febrile syndrome persisted, the presence of a large tumor mass was considered suggestive for transformation to a higher grade lymphoproliferation. The cardinal diagnostic procedure that offered

the correct diagnosis was splenectomy. It is debatable whether splenic tuberculosis was already present at the time of diagnosis and progressed with the onset of Alemtuzumab-induced lymphopenia or developed during treatment. We hypothesize that the defects in CD8+ mediated immunity and the predominant Th2 response determined the activation of a preexisting infection, while subsequent treatment-induced T-cell depletion permitted its progression and extension.

The high incidence of infection in Alemtuzumab treated CLL patients resulted in the development of guidelines for antiviral, Pneumocystis and antifungal prophylaxis. There are no current recommendations for preemptive mycobacterial therapy in high risk febrile patients.

CONCLUSION

We presented an atypical and rare case of splenic tuberculosis developed under mixed Alemtuzumab and CLL-related immune deficiency. Although Alemtuzumab treated patients are at high risk for CMV reactivation, the clinician should consider atypical micobacterial infection in the presence of prolonged febrile syndrome, especially in patients with poor socioeconomic status. It remains to be seen whether the low incidence of mycobacterial infection in high risk febrile patients will result in specific guidelines for diagnosis and monitoring.

THE CORRELATION BETWEEN ANTERIOR ISCHEMIC OPTIC NEUROPATHY THE NON-ARTHRITIC FORM, AND THE TREATMENT INVOLVING α-INTERFERON (Abstract). The Anterior Ischemic Optic Neuropathy is an uncommon complication of α-Interferon treatment, characterized by the either temporary or permanent diminishing in visual acuity. We are hereby presenting the clinical case of an Anterior Ischemic Optic Neuropathy (non-arteritic form) complicating interferon therapy for Chronic Hepatitis C. In such cases we recommend ophthalmological examinations and if severe ophthalmologic complications occur antiviral treatment should be stopped immediately. **Keywords:** ANTERIOR ISCHEMIC OPTIC NEUROPATHY, α- INTERFERON, VIRUS C PERSISTENT CHRONIC TOXIC HEPATITIS

Interferons are glycoproteins that have multiple antiviral, antiproliferative and immunomodulatory activities and can be effective in the treatment of hepatitis B and C, malignant melanoma, follicular lymphoma, *condyloma acuminata* (1,2).

Ophthalmologic complications with interferon therapy are rare, generally mild and transient(3).Optic neuropathy, retinopathy with cotton wool spots, hemorrhages, macular edema, trombotic microangiopathy occur in less than 1% of the patients (3).

The ocular complications are reported at the individuals with predisposing risk factors: diabetes, arterial hypertension, dyslipidemia(4).Systemic side effects due to interferon use are: flu-like syndrome, myalgia, rash, hypotension, thrombocytopenia, depression, anemia, peripheral neuropathy(1,3).

CASE

We've examined patient B.E, aged 64, a retiree, living in Iaşi. The patient was admitted on March 23rd, 2013, for the following symptoms: a progressive diminishing in visual acuity at R.E. for approximately two weeks, and the peripheral narrowing in her visual field at the O.U. The patient men-

tioned that she had been diagnosed some 36 months prior to her admission, with virus C persistent chronic toxic hepatitis, and then she had been under treatment with α- Interferon (IFN-PEG 2α, 180 mcg/ml/ weekly) for 2 months and with Ribavirin (1.200 mg/ daily). Her general pathological history was: Virus C Persistent Chronic Toxic Hepatitis, High Blood Pressure Stage III, Chronic Vestibular Syndrome, Multiple Lacunar Cerebral Infarctions. The patient had no previous visual problem. The biomicroscopic exam: normal. Visual acuity R.E. 1/3, L.E.1. Cromatic sense: R.E. red-green axis dyscromatopsia, L.E. normal. R.E. relative afferent pupillary defect, L.E. normal. The ophthalmoscopic exam: R.E. diffuse hyperemic optic nerve papilla, indefinite contour, edematous, peripapillary hemorrhages, "flaming", of small dimensions in the inferior temporal zone, narrowed arteries, veins dilated, Salus-Gunn sign, testing positive for foveolar reflex macula; L.E. optic nerve papilla of clear contour, temporally pale, narrowed arteries, veins dilated, Salus-Gunn sign, testing positive for foveolar reflex macula. The intraocular pressure: P.R.E. 14 mmHg; P.L.E. 16 mmHg. The anamnesis data, the general and the overall ophthalmologic clinical exam are pointing to the following probable diagnosis: O.U. Anterior Ischemic Optic Neuropathy Non-Arteritic Form, Secondary α-Interferon.

Other complementary explorations were: visual field, M.R.I., carotid and temporal arteries Doppler ultrasonography.

At the M.R.I. native exam (M.R.I. Nr.725/30.05.2013), no suggestive M.R.I. modifications were shown, on either M.A.U, P.E.I.C, A.V.C. or cerebral edema. The orbit, the optic chiasm, the optic strips were found to be within normal limits. Some cerebral atrophy, more prominent in the frontal-temporal area, bilateral, asymmetric.

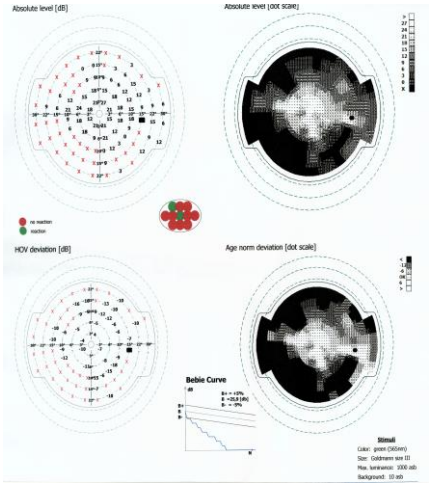

Fig. 1a. V.F.R.E. lower and upper arcuate scotoma, with a narrowing in the visual field fixed at 10^0 in the nasal sector, and 15^0 temporal ocular fixations

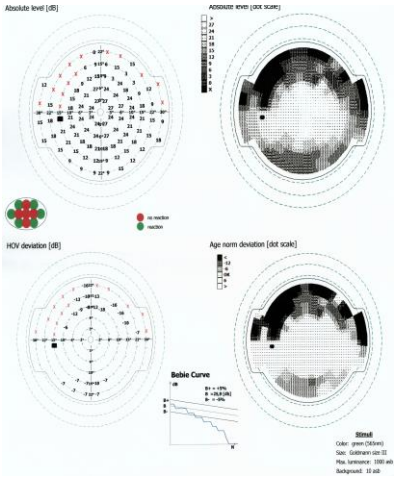

Fig.1 b. V.F.L.E. lower paracentral scotoma, upper arcuate scotoma

Laboratory investigations: VSH 90 mm/h, CRP 64 mg/l, Erythrocytes

$3.08.10^3.10^3/\mu L$, Hemoglobin 10,2 g/dl, Haematocrit 31,5 %, Average Erythrocytes volume 102/fl., Average Erythrocyte Hemoglobin 33/pg, Lymphocyte 1 x $10^3/\mu L$, mean Platelet volume 7,6/fl, Lymphocyte 23,8%, Urea 75,8 mg/dl. The internal medicine exam established the following diagnoses: C Virus Chronic Persistent and Toxic Hepatitis, Hypertension in the 3rd degree with great additional risk, Macrocytic Hypochromic Anemia, Multiple Lacunar Cerebral Infarctions, 1st degree Obesity, Sequel Pulmonary Tuberculosis. It was recommended: low in lipids and low in soda diet, treatment with Metoprolol 100 mg/dayly, Indapamide 1.5 mg/dayly, Ribavirin 1.200 mg/dayly, α-Interferon 180 mcg/ml/weekly, Acetylsalicylic Acid 75 mg/daily. The patient refused the temporal artery biopsy (no clinical sign of irregulary enlarged and ropey appearance of the temporal arteries was noticed).

The carotid and temporal arteries Doppler ultrasonography did not highlight any obstructive modifications at the carotid and temporal artery levels, indicative of a carotid obstructive syndrome and for the Anterior Ischemic Optic Neuropathy the Arteritic Form. The Otorhinolaryngology exam did not highlight neither acute nor chronic inflammatory process in the vicinity.

Following every investigation, the visual loss was decided to be due to α-Interferon therapy and the positive diagnosis takes shape: O.U. Anterior Ischemic Optic Neuropathy Non-Arteritic Form, Secondary α-Interferon; C Virus Persistent Toxic Chronic Hepatitis; Macrocytic Hypochromic Anemia; Multiple Lacunar Cerebral Infarctions, Atherosclerotic Hypertension in the 3rd degree, of very high risk; 1st degree Obesity; Sequel Pulmonary Tuberculosis. The diagnosis is being backed up by: the visual loss, the ophthalmoscopic exam (hyperemic disc edema), the visual field changes, the chronic treatment with α-Interferon, the risk factors (arterial hypertension, obesity), M.R.I., carotid and temporal Doppler ultrasonography.

The differential diagnosis

The papillary edema differential diagnosis is by the ischemic optic neuropathy arteritic form, non-arteritic form, toxic, optic neuritis, pseudo-syndrome Foster Kennedy.

Treatment

Throughout hospitalization, the patient was administered the following: systemic corticosteroids and antibiotics, vitamin therapy (B_1, B_6), aspirin, neurotrophics.

EVOLUTION

One month later, the evolution under treatment was favorable: V.A.R.E. 2/3, V.A.L.E.1, the optic disc edema partially resolved, resorption of the peripapillary hemorrhages, but the visual field did not improve. The prognostic under treatment: cautious. It was recommended a treatment with peripheral vasodilators, neurotrophic, aspirin, antihypertensive and the interruption of α-Interferon treatment immediately.

The antiviral treatment (α-Interferon 180 mcg/ml/weekly and Ribavirin 600 mg/daily) was not stopped and the patient experienced seven months later a relapse of optic neuropathy of controlateral eye. Ophthalmologic examination showed: the visual acuity L.E. 1/500, R.E. 2/3; L.E., hyperemic optic disk edema with peripapillary hemorrhages, R.E. optic nerve papilla of clear contour, temporally pale, L.E. relative afferent pupillary defect, O.U. red green dyschromatopsia. Laboratory investigations: VSH= 48 mm/1h, RBC=

3,68/$10^{3x}10^3$/µl, TGP= 93 U/L, TGO= 42 U/L, Fibrinogen= 351µg/dl, CRP = 1,1 mg/L. IgM, IgG for *Borrelia, Toxoplasma, Toxocara* was negative. Complementary explorations were: L.E. constricted visual field at 5^0 ocular fixations, R.E. constricted visual field at 5^0 in the nasal sector and at 10^0 in the temporal ocular fixation; fluorescein angiography (fig. 2).

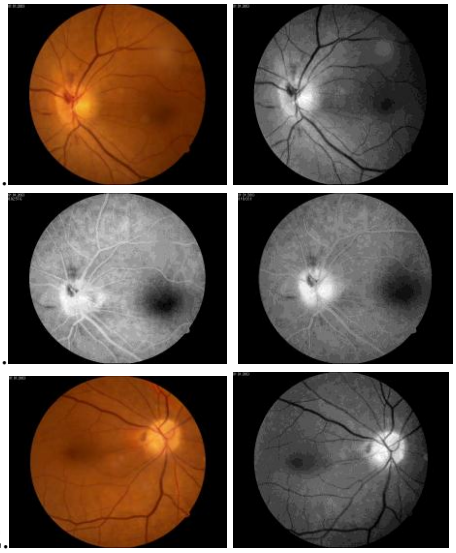

Fig. 2. Flourescein angiography revealed: L.E. blocking retinal flouerescence flame-shaped hemorrhages; O.U. hiperflourescent papillary growing in intensity until the late phase

The treatment was: intravenously metilprednisolone therapy, followed by oral metilprednisolone one mg per kilogram body weight for ten days, followed by tapering, vitamin therapy (B1,B6), aspirin, neurotrophics. The recommendation was the rapid cessation of α-Interferon therapy. One month later, the ophthalmologic examination showed: visual acuity L.E. 1/8, R.E. 2/3, L.E. optic disk edema partially resolved, O.U. red-green dyschromatopsia.

DISCUSSION

The Anterior Ischemic Optic Neuropathy is either a idiopatic or secondary ocular condition. The World Health Organization criteria recommends that AION (non-arteritic form) associated with α-Interferon therapy is "possible" (1).

The literature reports few cases of AION (non-arteritic form) during antiviral treatment for chronic hepatitis C (2 cases), cancer (2 cases), treatment of primary trombocytemia (1 case), malignant melanoma (1 case), amyotrophic lateral sclerosis (5).

The mechanism for how α-Interferon could cause AION (non-arteritic form) is unknown(1); the underlying immunologic mechanism has been suggested. It has been proposed that interferon is able to produce auto antibodies leading to the depositions of immune complexes in the small retinal or optic arteries (6).

The α-Interferon is causing the formation of cryoglobulin, rheumatoid factor, anticardiolipins antibodies (7).

Interferon has immunomodulatory properties capable of stimulating the production of various interleukins that can cause an inflammatory response affecting the blood vessels, leading to ischemia (8).

CONCLUSIONS

AION (non-arteritic form) secondary α-Interferon therapy may occur in rare cases, but the clinicians should be aware of the possible association and recommend interruption of the antiviral treatment.

Our patient received corticosteroids, with favorable course of visual function; the interferon therapy was stopped immediately after the relapse.

We suggest that the patients who would receive interferon therapy should have ophthalmologic examinations before starting and during the treatment and to discontinue or stop the α-Interferon treatment, if serious ocular implications occur.

LASER TREATMENT OF ONYCHOMYCOSIS

The efficacy of 1064nm Nd:YAG laser for the treatment of onychomycosis was investigated by Noguchi *et al*. The study included 12 patients with onychomycosis caused by *Trichophyton rubrum* and *T. mentagrophytes*, confirmed by fungal culture and/or real-time PCR. The laser therapy was applied in 3 sessions at 4-week intervals, to a single hallux nail, with thickness at baseline <3mm and turbidity affecting <75% of the surface of the nail. The efficacy of the therapy was evaluated 6 months after the first treatment: the nail turbidity significantly improved in 3 cases (>70%), while in 2 cases turbidity improved 50-70%, in one case it was slightly improved (30-50%) and in 5 cases there was no change in turbidity (<30% improvement) ; in one case, the turbidity was worse. Overall, there was a decrease in the turbidity of the total lesion area from 664.4mmto 481.0mm and a 27.6% improvement. The study concluded that the 1064nm Nd:YAG laser therapy is well tolerated and can be used as an alternative for treatment of mild onychomycosis (Noguchi H, Miyata K, Sugita T, Hiruma M et al. Treatment of Onychomycosis Using a 1064nm Nd : YAG Laser. *Med Mycol J*. 2013;54(4):333-9).

APPROACHING FRAILTY AS THE NEW GERIATRIC SYNDROME (Abstract): Ageing is inevitably associated with a decline in physiologic reserves. Frailty results from reaching a threshold of decline across multiple organ systems. By consequence, it is associated with a high vulnerability and reduced ability to maintain homeostasis. This vulnerability is not only age-related, but also related to disability and comorbidity, as illustrated by three clinical cases. Sarcopenia, which is defined as age-related loss of muscle mass, is considered to be a central manifestation of frailty. In addition to being highly prevalent in elderly population, frailty also exerts a substantial impact on quality of life. As it is extremely challenging by defying conventional medication and involving new therapeutically approaches, frailty fully qualifies as a new geriatric syndrome. **Keywords**: GERIATRIC SYNDROME, SARCOPENIA, FRAILTY SYNDROME

Just a word in the dictionary thirty years ago, frailty has become one of the most researched fields in the medical world. Over the years, it has had many definitions and different screening methods; nonetheless, all authors considered that frailty should have a multi-dimensional approach, involving a variety of psychological, social, emotional and spiritual elements, in addition to the physical ones (1-5).

Frailty is a clinical state of high vulnerability and reduced ability to maintain homeostasis, which is correlated with age and characterized by a decline of functional reserves which involve multiple organs and systems (6, 7). This vulnerability is not only age-related, but also related to disability and comorbidity. If disability is the result of the dysfunction of one or more systems, frailty is always an accumulation of multi-systemic dysfunctions. Disability is not always associated with instability, whereas frailty is always accompanied by this (8). All these three notions, though, often intertwine. Each of them has different prognosis on long term and needs a different therapeutic approach, this emphasizing the importance of their discovery and individual approach.

The cornerstone of frailty is sarcopenia, the loss of muscle mass and strength in aging population. Physiologic age-dependent changes (drop in growth hormone (GH), IGF-1, menopause/andropause) explain the impaired protein synthesis, the decline of muscle mass, strength, and bone density. Harmful consequences of sarcopenia in old age are loss of muscle

strength, inducing itself loss of mobility, neuromuscular impairment, and homeostatic balance failure syndrome with gait and balance disorders (9, 10). Sarcopenia increases the risk of falls and fractures – immobilization and its dreaded consequences, interferes with the nutrition skills (empty refrigerator) and malnutrition and favors the decline of the protein reserve of the body with diminished capacity to meet the extra demand of protein synthesis associated with disease and injury (11). Frailty is a part of all these different "vicious loops" including sarcopenia, neuromuscular impairment, falls and fractures, immobilization, malnutrition, impaired protein synthesis, and decreased protein reserve of the body (9).

In addition to being highly prevalent in elderly population, frailty also exert a substantial impact on quality of life. It is a multifactorial condition in which many risk factors interact and affect different organ systems, influencing clinical presentation, course of disease(s) and outcome of elderly patient. As it is extremely challenging by defying conventional medical wisdom and crossing traditional clinical boundaries, frailty fully qualifies as a new geriatric syndrome (7).

Lang PO, et col. (12) describes 3 stages of frailty. The preclinical stage encompasses the situations when the organism has enough physiological reserves to correctly respond to stressors (acute onset of a disease or aggravation of a previous one, physical or psychological trauma); in this stage recovery should be complete. In the stage of clinical frailty, the functional reserves are insufficient and the recovery is incomplete. The final stage is that of frailty complications, resulting from physiological vulnerability and reduction of functional reserves. This last stage leads to a high risk of falls, disability, polimedication, long-term hospitalizations, severe infections, institutionalization and death.

The clinical diagnosis of frailty is based on a multitude of signs and symptoms, such as weakness, fatigue, ponderal loss, decreased capacity to maintain balance, low level of physical activity, loss of motor performance, social withdrawal, mild cognitive disorder and growth of vulnerability to stress. There were several approaches to identify frailty. One was developed by Rockwood K, et col. (13) and consists of measuring deficits across many different types of health conditions: functional, clinical, and physiological. A second approach considers that frailty has a distinct pathophysiology and its own clinical presentation (14). Fried LP, et col. (15) defined a phenotype of frailty with the following features:

- unintended loss of weight (4-5 kg in a year);
- self-reported exhaustion;
- decrease of muscle strength (reduced grip strength, less than 20% in dominant hand);
- slowing down of walking speed (less than 20% for the walking time of 4,5 m);
- reduction of physical activity (less than 20% of caloric expenditure).

Meeting three out of five criteria define the frail elderly. There also has been identified a sub-clinical form, pre-frail, characterized by meeting one or two out of five criteria, this state having a high risk to progress to manifested frailty.

This phenotype, being the basis of screening methods and diagnosis in clinical practice, includes only the physical component of the syndrome, though neglecting other domains, such as physical and social

components. Thus, numerous new diagnosis scales of frailty have been developed which contain all components, such as the Canadian Study of Health and Aging (CSHA) Frailty Index, Edmonton Frail Scale, Groningen Frailty Indicator (16, 17).

A new system of biomarkers has been identified which could provide the early diagnosis of frailty: IL-6, TNFα, PCR, Ciliary Neutrophic Factor (CNTF), etc. However, recent studies (18, 19, 20) agree that the best evaluation and classification of frailty is made by the complete geriatric assessment.

To exemplify frailty as a geriatric syndrome, we have chosen 3 representative clinical cases, of patients hospitalized in the Geriatric Clinic of „Dr C. I. Parhon" Hospital, Iași.

Patient 1 is a 81 years old female who has been recently diagnosed by the general practitioner with pneumonia and treated at home with antibiotics. The evolution was not favorable and she was admitted in our clinic. She had dyspnea, cough with mucopurulent sputum, sweating, nausea, weight loss (approximately 5 kg in the last year), and fatigue. She had a history of hypertension, angina with left bundle branch block, and stroke with secondary right hemiparesis. She lives in the countryside with her family and she benefits from family support. The MRC (Medical Research Council) Scale for Muscle Strength for lower limbs and right upper limb = 4/5. The Groningen Frailty Indicator (GFI) = 8/15 points. Comprehensive geriatric assessment showed a high risk of malnutrition (MNA = 16/30 points) and an almost complete need for care for daily activities (ADL) and for instrumental daily activities (IADL). Need for assistance has increased from the moment of aggravation of respiratory disease and the 3-days bed rest. The patient has geriatric frailty syndrome neglected in the last year and aggravated progressively in the last 3-4 days.

Due to the multidisciplinary approach (correct and complete medical treatment, correct diet, physical therapy and adequate family support) she did very well during hospitalization: she acquired autonomy for ADL and decreases the level of assistance for IADL, she started to eat on her own and had a weight gain of 2 kg. She started to walk, first with the support of the family members and with a walker when discharged home. Later reevaluations showed that she maintained a good functional and nutritional baseline.

Patient 2 is a 77 years old female from an urban area. She was referred to our clinic by ambulance for fatigue, excessive sleepiness, temporal-spatial disorientation, intense pallor, and weight loss of approximately 10 kg in the last year. She has been living alone in a flat since her husband died 4 years earlier but she has a caregiver who comes every day. The family noticed depression and loss of appetite, refusing food for the last couple of weeks. She had a history of diabetes, hypertension and anemia but without any medical records. The very first investigations showed severe macrocytic anemia which requested several blood transfusions.

Comprehensive geriatric assessment was performed after the management of the acute episode. She had a mild cognitive impairment (MMSE = 23/30 points), malnutrition (MNA = 17/30 points) and clinical frailty (GFI = 9/15) but no depression. She did well during hospitalization with the help of the multidisciplinary team: she resumed feeding, initially with the help of the family and caregivers, later on her own. She started to

walk under the supervision of the kinetotherapeut, initially for short distances with bilateral support, then longer distances with the help of a cane. She gained weight, approximately 3 kg. In 6 months time she surpassed her previous functional and psychological baseline, mostly due to correct multidisciplinary approach and increased family support that motivated her to fight frailty and win the battle.

Patient 3 is an 85 years old female from the rural area. She was admitted for intense fatigue, weight loss of approximately 10-12 kg in the last year and edema. She had a history of atrial fibrillation and osteoarthritis. She had no family and lived alone. GFI = 6/15 points. Comprehensive geriatric assessment showed: the MRC for lower limbs is 3/5 (can walk but prefer to stay in bed), malnourishment (MNA = 15/30 points), needs assistance for IADL, mild cognitive impairment (MMSE = 24/30 points). We started a complex therapy, including nutritional assistance, physical therapy, adequate medication and psychological support but she deteriorated progressively, developed multiple organ insufficiency probably secondary to urinary sepsis and she died after 11 days of hospitalization.

DISCUSSION

We consider that these 3 cases are illustrative for the frailty syndrome. Even if the three patients had different pathologies, they still had several common features: weight loss, no physical activity, fatigue, different degrees of depression and mild cognitive impairment. All these represent the frailty phenotype observed as being more or less pregnant with the three patients described earlier.

Our first patient is a clinically frail lady with important cardiovascular pathology hospitalized for an acute infectious episode (pneumonia). She recovers well due to simultaneous treatment of both acute episode and frailty. The constant and active family support during recovery was definitely a very important factor in regaining patient's autonomy. The evolution of the acute pulmonary infection has been influenced more by the degree of frailty than by the preexistent cardiovascular condition.

The second patient had a more severe class of frailty so her recovery was not as good as in the previous case. It is to be noticed that frailty is a negative predictor in the evolution of geriatric patient and leads to comorbidity aggravation.

The third case represents an obvious frail elderly lady with a series of adverse events (lives alone, has no family) but no major comorbidities. Still, she didn't cope with this new stressor (urinary infection) despite the correct, multidisciplinary treatment applied.

These cases suggest that frailty is a continuum, ranging from latent physiological alterations to clinically manifest syndrome. This phenotype plays an important role in the outcome of elderly patients. Applying frailty scores systematically to elderly population could lead to early discovery and identifying the stage of frailty and early interventions to this syndrome, which can make a difference between autonomy and dependence, between being active and confined in bed and, finally, between an optimal quality of life and 'the burden of old age'.

Comprehensive geriatric evaluation is considered 'golden standard' for identifying frail, vulnerable individuals, preferably before the adverse outcomes of frailty itself occur. If frailty appears to be the primary

condition, the goal would be: prevention of muscle loss and improvement in strength and balance, preservation of fat-free mass, prevention of sarcopenia and balanced nutritional intake. The easiest way to prevent or to delay frailty is to prescribe regular physical exercises associated with additional nutritional supplementation (21, 22). In our experience, family support is of outmost importance in maintaining a good quality of life for the elderly persons is a strong motivation to keep them independent and is a strong impulse to fight all adverse outcomes of aging: disability, dependency, falls, acute illness, hospitalization. Frailty is a geriatric syndrome and it became the cornerstone of modern geriatric medicine; identifying and establishing a personalized preventive strategy for frailty is not only a need but also a responsibility.

THE RELATIONSHIP BETWEEN CARDIOVASCULAR DISEASES AND PERIODONTITIS

A recent study conducted by Khosravi Samani M and collaborators from the Department of Periodontics - Babol University of Medical Sciences - Iran aimed to investigate a possible relationship between cardiovascular diseases and periodontitis. In the study were included 60 patients with myocardial infarction as study group and 63 subjects with periodontitis without myocardial infarction as control group. The mean ages of patients in study and control groups were 54.97±9.68 and 55.89±11.9 years, respectively. Periodontitis was evaluated according to Ramfjord periodontal diseases index and also according to the number of missing teeth. The classic risk factors of myocardial infarction were recorded. The obtained data revealed that the patients who lost more than 10 teeth presented more risk of myocardial infarction (odds ratio of 2.73). A significant relationship between mean attachment loss and myocardial infarction (p=0.0001) was established. A relation between attachment loss more than 3 mm and myocardial infarction with odds ratio of 4 was established. Significant difference between mean periodontal disease index was seen in both groups (p=0.0001). Subjects with periodontal disease index more than 4 were at more risk of periodontal diseases (odds ratio of 7.87). The results obtained by the authors revealed the presence of significant relation between periodontitis and myocardial infarction which could serve as an alarm signal to treat periodontitis with great care. (Khosravi Samani M, Jalali F, Seyyed Ahadi SM, Hoseini SR, Dabbagh Sattari F. The relationship between acute myocardial infarction and periodontitis. *Caspian J Intern Med*, 2013; 4 (2): 667-671).

2. Pulmonary Rehabilitation Clinic

PULMONARY REHABILITATION – FROM GUIDELINES TO PRACTICE (Abstract): Pulmonary rehabilitation is an integral part of clinical management and health maintenance of patients with chronic respiratory disease who remain symptomatic or continue to have decreased function despite standard medical therapy. It is a spectrum of evidence-based, multidisciplinary, and comprehensive intervention for patients with chronic respiratory problems. Most evidence for the efficacy of respiratory rehabilitation is for patients with chronic obstructive pulmonary disease but there are encouraging results for extending its indications. Current programs of pulmonary rehabilitation are based on guidelines which formally grade the level of scientific evidence and on practical recommendations developed by several prestigious societies. The main components of a pulmonary rehabilitation program are patient selection and assessment, exercise training, education and self-management of the disease, psychosocial and behavioral intervention, nutritional support, outcome assessment and enhancement of long-term adherence to the rehabilitation recommendations. Exercise training is the central component of respiratory rehabilitation, aiming at physical reconditioning, and upper and lower limb muscle training, using several strategies to optimize training. Outcome assessment is an integral part of the program including the measurement of several valid, interpretable and easy to administer parameters. The beneficial effects of pulmonary rehabilitation are the improvement of dyspnea and degree of physical and social disability, less hospitalizations and exacerbations, better overall quality of life by increasing independence.
Keywords: GUIDELINES, PULMONARY REHABILITATION, PROGRAM.

According to the current definition, pulmonary rehabilitation is "an evidence-based, multidisciplinary, and comprehensive intervention for patients with chronic respiratory diseases who are symptomatic and often have decreased daily life activities. Integrated into the individualized treatment of the patient, pulmonary rehabilitation is designed to reduce symptoms, optimize functional status, increase participation, and reduce health-care costs by stabilizing or reversing systemic manifestations of the disease" (1,2).

Pulmonary rehabilitation has become a standard of care for patients with chronic lung diseases. The current evidence-based guidelines for diagnosis, management and prevention of these diseases (3) reffer to pulmonary rehabilitation patients with chronic obstructive pulmonary disease

(COPD). In the last years was assessed the role of rehabilitation programs in chronic lung diseases other than COPD: pulmonary fibrosis (4), primary pulmonary hypertension (5), before and after pulmonary surgery (lung transplantation) (6), the results being encouraging for expanding the indications of such programs.

The practical need for pulmonary rehabilitation occurred because patients with a chronic respiratory disease are highly symptomatic, need frequent hospitalizations, are physical deconditioning, and have a significant psycho-social dysfunction, all of which are accompanied by a significant decrease in their quality of life. From these observations it also came out the particularity of rehabilitation intervention, namely that it primarily addresses the subjective aspects of the disease, represented by the persistence of symptoms and the degree of disability (7).

In 2006 was published a joint statement on pulmonary rehabilitation of the European Respiratory Society (ERS) and American Thoracic Society (ATS) (2) this being complementary to other two major documents: the evidence-based guidelines of the American College of Chest Physicians (ACCP) and American Association of Cardiovascular & Pulmonary Rehabilitation (AACVPR) (8), which formally graded the level of scientific evidence, and AACVPR guidelines for pulmonary rehabilitation programs that offer practical recommendations (9). Updated evidence-based clinical practice guidelines for pulmonary rehabilitation, published in Chest in 2007 (10), AACVPR guidelines in 2010 (11) and the Canadian Thoracic Society guidelines (12) are added. These guidelines should be implemented by a multidisciplinary team that covers all the aspects of a comprehensive rehabilitation program and could be performed in all settings, including hospital inpatient, outpatient or even home in order to maintain the favorable results of respiratory rehabilitation (13).

COMPONENTS OF PULMONARY REHABILITATION PROGRAM

According to the guidelines, the main components of a pulmonary rehabilitation program are patient selection and assessment, exercise training, education and self-management of the disease, psycho-social and behavioral intervention, nutritional support, outcome assessment, and enhancement of long-term adherence to the pulmonary rehabilitation recommendations (2, 10, 11).

❖ Patient selection and assessment

Based on current evidence pulmonary rehabilitation should be considered primarily for the symptomatic COPD patients, presenting with reduced exercise capacity and decreased daily life activities but other patients with chronic respiratory disease and impairment can also be referred for achievement of some beneficial effects (14) (tab. I).

Concurrent diseases or conditions such as severe cardiovascular diseases, disabling neurological or orthopedic conditions may negatively interfere with physical training program while cognitive dysfunction and severe psychiatric disorders prohibit cooperation and understanding, being considered exclusion criteria.

Before entering a pulmonary rehabilitation program, patients should be complexly assessed in order to develop a strictly individualized program tailored to the patient's needs for maximal benefits (14) (fig. 1).

TABLE I

Pulmonary diseases appropriate for pulmonary rehabilitation

OBSTRUCTIVE LUNG DISEASE	RESTRICTIVE LUNG DISEASE
Chronic obstructive lung disease	*Interstitial diseases (interstitial fibrosis, sarcoidosis, occupational lung disease)*
Asthma	*Neuromuscular diseases (Parkinson's disease, amyotrophic lateral sclerosis, multiple sclerosis)*
Bronchiectasis	*Chest wall diseases (ankylosing spondylitis, kyphoscoliosis)*
Cystic fibrosis	
OTHER PULMONARY CONDITIONS	
Lung cancer	
Primary pulmonary hypertension	
Obesity-related respiratory disease	
Before and after thoracic and abdominal surgery	

Clinical elements such as orthopnea, behavioral signs associated with pain (antalgic position, grimacing), dyspnea scales (mMRC scale - *modified British Medical Research Council*, modified Borg scale) and pain scales (visual analogue, verbal numerical scales) are used in order to assess these two symptoms that may directly affect patient's ability to follow the physical training program, thus reducing the benefits of the rehabilitation program (14).

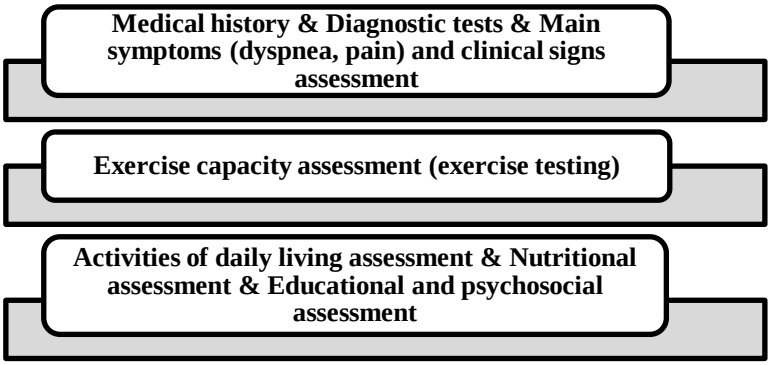

Fig. 1. Main steps in the assessment of patients included in pulmonary rehabilitation programs (14)

Exercise capacity is determined through incremental exercise tests on cycle ergometer or treadmill or through field tests, particularly the 6-minute walk test, and the guidelines for its application reducing the variability in administration of the test (15). This stage of assessment is crucial for the correct prescription of physical training level in the setting of respiratory rehabilitation program.

Initial assessment of activities of daily living (ADL) allows determining the degree of dependence of chronic pulmonary patients on family members or caregivers.

In recent years were developed questionnaires extremely easy to use by physicians and patients having a small number of items that cover all key elements with impact on the quality of life of patients with lung diseases, such as CAT (*COPD Assessment Test*) (16,17) and ACT (Asthma Control Test) (18), the Romanian version of these questionnaires being validated.

❖ **Exercise training**

Exercise training is the central component of the comprehensive respiratory rehabilitation program and has three practical goals: physical reconditioning, respiratory muscle training and upper and lower extremities exercise.

The program is gradual and individualized, tailored to the patient's exercise performance under the supervision of a physician. Its benefits are increased exercise capacity, reduced ventilatory effort at submaximal work loads, and improved perception of dyspnea and fatigue, so common in patients with chronic lung diseases. In addition, sequences of high-intensity training result in an anabolic stimulus and improve oxidative capacity of the skeletal muscles, their dysfunction being improved gradually (19).

Physical reconditioning aims at achieving a sensation of „well-being" and improving the chances of survival. Physiologically, this is achieved by increased maximal oxygen uptake, improved tissue oxygen utilization, increased skeletal muscle strength and endurance, improved motor coordination and change in body composition with loss of adipose tissue in favor of muscle mass (19).

These benefits are achieved by selecting the adequate intensity, frequency and duration of training sessions, and by maintenance strategies following pulmonary rehabilitation in order to slow benefits' decline after stopping the program.

There is still controversy over the best parameters for training sessions, but the evidence-based recommendations suggest an intensity of 50% -70% of the predicted maximal heart rate or peak oxygen uptake, session duration of 30 minutes, and a frequency of 3-4 sessions /week for 6-12 weeks (1, 7, 10, 12, 19).

Given the resting tachycardia and severe skeletal muscle dysfunction in patients with chronic respiratory diseases some authors have proposed the use of dyspnea ratings instead of heart rate to guide exercise training intensity, and a two-phase training, intensive training followed by maintenance training, in order the benefits to last longer (19,20). Also, there are several strategies to optimize physical training of these patients: use of optimal bronchodilator therapy, oxygen supplements whether desaturation is present or not, administration of helium gas mixtures, application of noninvasive mechanical ventilation, respiratory muscle training, neuromuscular electrical stimulation, extension of the training program beyond 12 weeks, and combined resistance and aerobic exercise (1, 12, 19, 21).

Lower-limb muscle training leads to increased walking distance, improved peak oxygen consumption, and even reduces the severity of dyspnea when performed at an intensity of 60-80% of maximal work capacity as determined by an exercise test, with close monitoring of heart rate and dyspnea. Exercise intensity is progressively increased during a 24-session training cy-

cle. Studies on this issue of physical training in patients with chronic pulmonary disease had conflicting results, some showing benefits across all stages of disease, others only in those with mild to moderate impairment (22).

Upper-limb muscle training is beneficial in strengthening scapular belt and upper chest wall muscles, thus improving the traction force applied on the thoracic cage during inspiration in this patient in which diaphragm functions in ventilatory mechanics are affected. The best results are obtained with supported arm ergometry training, performed 20 minutes/session, at 60% of maximal work capacity as assessed by an exercise test. Also beneficial is the method for unsupported arm training, consisting in lifting dowels (weight = 750 g) to shoulder level in the rhythm of breathing rate and progressively increasing its weight by 250 g/week. Each session dyspnea and heart rate should be monitored (11, 14).

❖ **Education and self-management**

Education delivery in pulmonary rehabilitation is performed individually or in small groups and is focused on behavioral modification of both the patient and his/her family members in order to achieve active involvement.

Any educational intervention should begin with a basic simple to understand overview of the main physical and psychological changes occurring in chronic lung diseases and their evolvement over time. The patient should be advised to advanced planning, simplify and prioritize his daily activities so that in the early stages of the disease to be able to perform his job-related tasks and in the advanced stages to carry out activities of daily living (23).

For the purpose of energy conservation essential is the assisted acquisition of breathing, cough, and postural drainage techniques, particularly important in patients with hyperinflation (COPD patients) and/or in those with bronchial hypersecretion (bronchiectasis or cystic fibrosis). Relaxation and stretching techniques (yoga, Pilates) help to improve the patient's psychological distress and increase ventilatory coordination (24).

Essential in chronic pulmonary patient education is counseling and therapeutic support for quitting active smoking and avoiding exposure to secondhand smoke or other respiratory hazards. Also, the patient has to know how to self-administer the inhaled medication properly, how to use auxiliary devices (spacers), to be aware of the possible side effects and of the effects of drug abuse, concerning especially sympathomimetics, theophylline or antibiotics (tachyarrhythmias, elevated blood pressure, precipitation of angina episodes, microbial multiresistance). Proper use of long-term oxygen therapy and noninvasive positive pressure devices should also be explained to the patients with chronic respiratory disease.

❖ **Nutritional assessment and counseling**

Various studies have shown that weight loss in chronic respiratory patient is a poor prognostic indicator, especially in those with COPD. Alarming weight loss refers to the loss of more than 10% of body weight in the last six months or more than 5% in the last month and is particularly dramatic in disease exacerbations when food intake decreases, systemic inflammation is markedly increased, and energy balance becomes negative. On the other hand, obesity adversely affects respiratory function by increasing the load on the already compromised respiratory system (2, 14). Anthro-

pometric measurements of nutritional status are body mass index (BMI) and estimation of lean body weight by bioimpedance, a simple and noninvasive method (25, 26).

Nutritional counseling is aimed at achieving an adequate alimentary plan for achieving and maintaining an optimal weight including, if necessary, supplements in liquid form.

❖ **Psychosocial support**

Patients with chronic pulmonary disease commonly have psychiatric co morbidities, primarily anxiety and depression, generated by the difficulty of accepting their illness as well as coping with the associated physical and neuropsychological impairments having major adverse consequences on the quality of life (27). Assessment is done by clinically validated questionnaires and scales (Beck depression inventory and depression scale for geriatric patients) and the results are integrated into the multidisciplinary program of pulmonary rehabilitation (28).

The practical way of providing psychosocial support is to organize support groups focused on specific issues, group therapy and education, individual psychotherapy, stress reduction and panic control techniques with the permanent involvement of family members and caregivers (14, 21).

❖ **Outcome assessment**

Outcome assessment is an integral part of a comprehensive respiratory rehabilitation program and aims to quantify its beneficial effects (fig. 2).

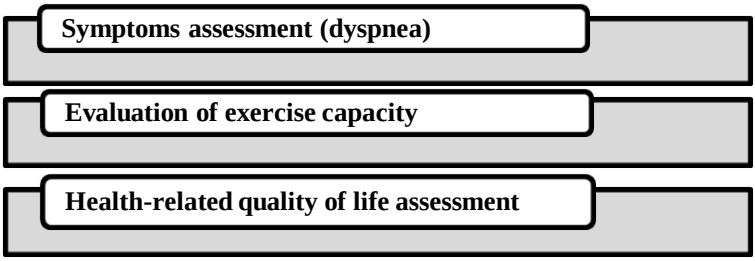

Fig. 2. The main objectives for outcome assessment in pulmonary rehabilitation program

The clinical practice use several types of measurements, validated in studies, easy to interpret and manage. To evaluate the dyspnea, the most severe symptom of patients with chronic respiratory impairment, are used dyspnea scales (Borg, mMRC), whichever is subjective improvement, which correlate with decreased ventilatory burden during exercise as a result of training (1, 2, 10).

Exercise capacity and its improvement after aerobic or resistance exercise training is assessed by conventional exercise testing, cardiorespiratory testing - which is more complex, or by the pragmatic option of field tests, the 6-minute walk test being the most commonly used and recording the increase in the walking distance – the estimated minimal clinically important difference being 54 meters (2, 10, 29). Pedometers have been introduced recently, being simple and portable devices that measure the number of steps and are useful in self-monitoring, progress assessment, and in enhancing compliance with the training program and activities of daily living (30).

Health-related quality of life is assessed using generic or disease-specific questionnaires, being commonly used in COPD. *St*

George's Respiratory Questionnaire (SGRQ) is one of the most frequently used questionnaires being designed for long-term studies and having well represented psychometric properties, the Romanian version being validated. In studies, SGQR score improvement was maintained even 1 year after the end of respiratory rehabilitation program (2, 10, 21).

CONCLUSION

Pulmonary rehabilitation is a dynamic evidence-based field of pneumology, which is an integral part of the current treatment of chronic respiratory diseases.

Respiratory rehabilitation programs follow the current guidelines, being delivered in inpatient or outpatient settings, their success depending on the skill and experience of the multidisciplinary team, socio-economic conditions, and adherence of patients and their families.

The most important benefits of pulmonary rehabilitation are the relief of symptoms, particularly dyspnea, improvement of complications, less and shorter exacerbations and hospitalizations, with significant cost-reduction, decreased physical and social disability, improved muscle deconditioning and increased exercise capacity, reduced anxiety and depression and improved emotional well-being, all these resulting in an improved overall quality of life for patients with chronic lung disease.

EPIDEMIOLOGICAL CHARACTERISTICS OF PERIPHERAL ARTERY DISEASE: A RETROSPECTIVE STUDY (Abstract): Peripheral artery disease (PAD) is a common condition. Over the past 20 years the risk factors for PAD have changed. **Aims:** To identify the regional characteristics of the patients with PAD and the sex- and urban/rural-related differences. **Material and methods:** Retrospective study on patients admitted to the Iasi "St. Spiridon" University Hospital in the interval 2007- 2012. The dataset was prepared for t student analysis in in view of determining statistical significance. **Results:** Of the 361,248 patients admitted to the 20 units of the hospital, 2,623 patients were diagnosed with advanced stages of PAD (Leriche - Fontain III and IV). Significant statistical differences were found between men and women, and between rural and urban men (p=0.001). 20.5% of the patients underwent amputations. **Conclusions:** This is one of the first studies that has identified urban/rural differences. The characteristics specific to PAD patients from North-Eastern Romania are presented. **Keywords:** PERIPHERAL ARTERY DISEASE, EPIDEMIOLOGY, RISK FACTORS.

Peripheral artery disease (PAD) is a major cause of disability, morbidity and mortality with a negative effect on the quality of life (1, 2). PAD is chronic, ischemic, with slowly-progressive. The patient adapts to the compromised arterial system by reducing oxygen demand and indirectly physical activity.

Standard therapy for PAD includes the administration of antiplatelet drugs (3,4) and a good control of the risk factors (smoking, dyslipidemia, diabetes, hypertension, etc.) (5) Antiplatelet therapy is usually combined with physical exercise that may help prevent or delay the onset of atherosclerosis. In advanced cases a wide variety of interventional surgical procedures are used to address specific findings in each individual case (5).

The prevalence of PAD increases with age, several epidemiological studies finding it in the range of 3% to 10 % (6), and 15% to 20% in persons over 70 years (7).

Many risk factors are involved in the development of PAD, their prevalence being higher in the male population. The most frequently involved risks are: sex, smoking, diabetes, hypertension and hyper-

lipidemia (8).

MATERIAL AND METHODS

We conducted a retrospective study including a total of 2623 subjects diagnosed with various forms and stages of PAD. The data were extracted from the database of "St. Spiridon" University Hospital (Iasi, Romania), covering the interval January 1, 2007 – January 1, 2012.

The data were statistically analyzed using *Microsoft Excel* and *IBM® SPSS® Statistics version 17.0*, and *Graph Pad Prism* for graphics.

The obtained data were organized into groups according to age, sex and urban/rural area to facilitate the analysis of treatment and laboratory data, by writing a Visual Basic macro in MS Excel. A descriptive statistical analysis was performed for the various subgroups. Student t test was used to compare the groups. This type of analysis is the best choice for analysis of small data sets specific to medical studies, for comparison with 95% confidence interval and α value of 0.05.

RESULTS

During the study interval a total of 361,248 patients were admitted to the 20 units of the hospital, Vascular Surgery, Cardiology, Internal Medicine included. Of these, 2,623 patients were diagnosed with PAD, totalizing 4869 readmissions during the study interval.

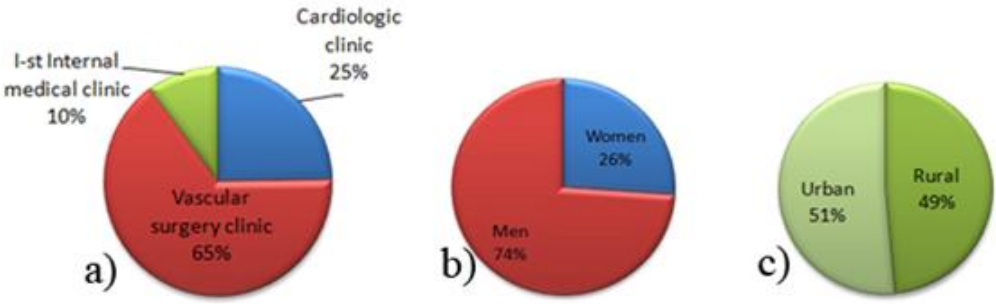

Fig. 1. Distribution of the PAD patients according to a) hospital unit b) sex, and c) urban/rural area

Of all PAD patients, 685 were women and 1938 men (fig. 1b.). All patients were caucasians and presented the classical urban/rural characteristics (fig. 1c).

The mean age of the study group was 64.5 years, and median age 66 years. Age distribution was bimodal (about 57 years and about 69 years) (fig. 2a). This trend suggests the presence of two different groups that need further analysis and separation (fig. 2b, c, and d).

Fig. 2b shows the age distribution by sex. Bimodal age distribution with a first peak at 57 years seen in the male population is almost absent in women (fig. 2b). Further, urban/rural distribution of women showed bimodal distribution in rural women while in the urban women the distribution is lognormal (fig. 2c).

In the male patients there was a clear rural/urban difference (fig. 2c). Urban patients had an obvious bimodal distribution

of the age at onset (57 and 70 years) while in the rural male patients the first peak was almost absent, as in urban women. Furthermore, in the urban patients the onset was at slightly older age.

The prevalence of PAD in men from rural areas was higher than in urban men, fact also confirmed by Student T test *(Paired Samples T Test)*, statistical significance p = 0.001, the same being true for women (p <0.05).

Smoking is one of the most important risk factors for peripheral arterial disease. We evaluated only the patients admitted to internal medicine units, a total of 1028 patients, of which 857 (83.4%) self-declared smoking or former smoking status. There is a clear male prevalence of smoking (p=0.001), while no rural/urban difference in smoking status was noticed (p = 0.753).

Laboratory tests showed an average fibrinogen level of 413 mg/dl, above the normal upper limit (200-400 mg/dl). Also average total cholesterol was 200 mg/dl, the normal upper limit. HDL-cholesterol was lower (average 38 mg/dl) than normal level (normal > 40 mg/dl).

Of the 2623 study patients 537 (20.5%) underwent amputation (fig. 4).

Surgical revascularization techniques were used in 782 (53.7%) patients, 424 (54.2%) requiring multiple revascularization techniques. A total of 1457 surgical procedures were performed in patients with PAD.

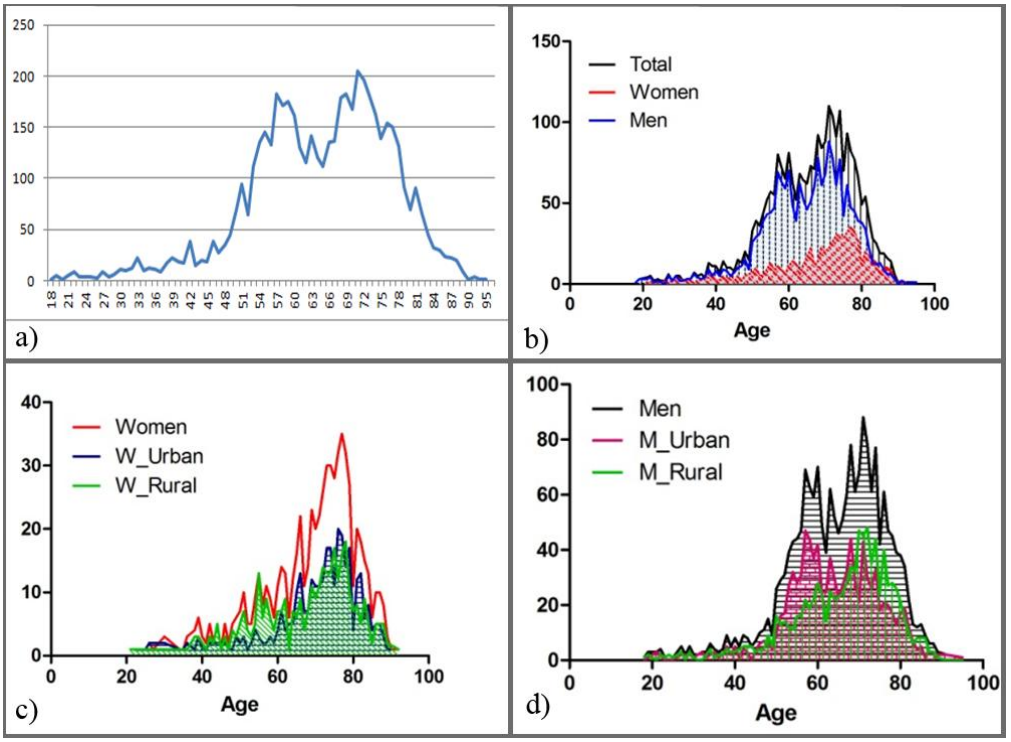

Fig. 2. Distributions of patients according to: a) age, b) sex vs. age, c) women age vs. urban/rural, and d) men age vs. urban/rural. The graphs are presented as age vs. patient frequency.

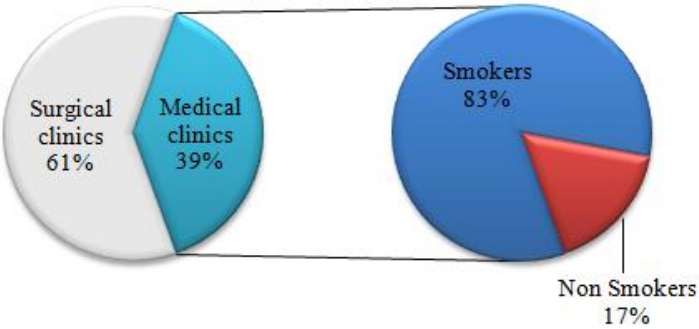

Fig. 3. Distribution of smoking patients

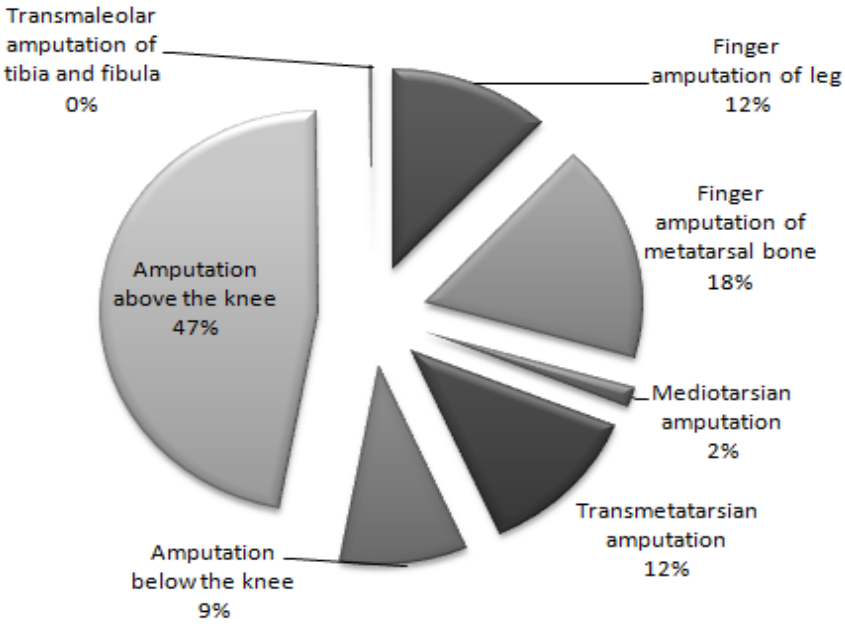

Fig. 4. Distribution of amputations performed in patients with PAD

In 602 surgical revascularizations (41.3%) synthetic or composite grafts were used, that required the association of anticoagulant therapy. In 338 (56.1%) amputations of the lower limb segments, and in 100 (16.6%) major amputations (thigh or calf) were performed.

DISCUSSION

Peripheral artery disease is known to be a disease affecting small and medium-sized arteries of the body, with a prevalence varying according to age and sex. In our study the prevalence PAD in the patients admitted to the Iasi "St. Spiridon" University Hospital Iasi was 1.35%; mean age of our patients was 64.5 years, very close to that reported by other studies (7).

The incidence of the disease in our study is lower than in other studies (9).

This difference may be explained by the late-stage presentation of most of our patients. All our patients were stage III or IV according to Leriche-Fontain classification.

The prevalence of PAD is higher in men than in women, fact not reported by previous studies. This can be explained by the socioeconomic status of our patients as demonstrated by the subgroups comparison. There are no statistically significant differences between women and men from urban areas. The high statistically significant difference between rural women and men areas ($p<0.001$) can be explained mostly by the fact that rural communities are traditional and religious, and smoking among women is rare.

A statistically significant difference ($p=0.001$) was found between rural and urban men. Thus, the onset of PAD is at a younger age in rural than urban males. This is mainly related to the rural life style and also very likely to socioeconomic status (10). It is confirmed by an obvious bimodal distribution (fig. 2d) with a first peak at a younger age (about 57 years) and an almost similar frequency at about 70 years. In the urban male population the onset at a younger age is much less obvious, while the second onset peak is at a slightly older age (about 72 years). Student T test showed that these data are statistically significant ($p = 0.001$), thus being a second characteristic never described by other studies.

Laboratory tests showed no differences between study groups except for hemo leukogram that detected higher red blood counts and hemoglobin concentrations in the smokers.

Several studies have demonstrated that amputation rate is 1-7% in patients with 5 to 10 years of persistent claudication. And only one patient out of four will complain of worsening symptoms (11).

There is no evidence that shows that patients with symptomatic PAD have a more rapid progression as compared with asymptomatic patients, and it was found that variations in disease symptoms are related to patient activity level.

CONCLUSIONS

Chronic ischemia of lower limbs has a high prevalence, and it is often under diagnosed. Its prevalence increases with age, and in the Moldavian rural population the onset is at a younger age. In this study we found that of the total number of patients admitted for vascular conditions, 1.4% had chronic ischemia. In these patients the disease is in advanced stages, and 60% of them require revascularization surgery or amputation.

In Iasi County, an estimated 5% of the total population (723,553 according to the 2011 census) has peripheral artery disease (over 36000 persons).

Another observation based on our study is the increased prevalence of PAD in men as compared to women, finding reported by few studies. This may be accounted for by the fact that women have later onset of PAD and a different lifestyle than men.

Under these circumstances, primary prevention of PAD is ineffective. It is a consequence of the fact that asymptomatic patients with critical ischemia do not present to a physician, and thus do not benefit from an early treatment and avoidance of complications in later stages.

The question why PAD has a younger age onset in urban men and rural women needs to be answered. This may require collaboration with the National Institute of Statistics for identifying: (i) the possible relationship between age of onset and under-

development (ii) relationship between geographical areas and regional infrastructure, (iii) relationship with unemployment, etc.

In further studies we plan to map geographically PAD prevalence in order to identify the regions where maximum attention should be given to prevention and screening.

PARTICULARITIES IN DIAGNOSIS AND TREATMENT FOR INFECTIOUS ENDOCARDITIS IN CHILDREN (Abstract): Infectious endocarditis (IE) represents a rare pathology in children, but with lethal potential. The goal of the therapy is fast and total eradication of the infection. **Aims**: To study particularities in diagnosis and treatment for infectious endocarditis in children. **Material and methods:** Children with infectious endocarditis hospitalized between January 2007 - February 2012 in the Cardiology Department of the „Sfânta Maria" Children Emergency Hospital of Iasi have been included in the study. **Results**: The patients are aged between 23 days and 16 years, the average age being 4 years old. At approximately 88% of the patients (14 cases), the endocardial damage appeared in the pre-existent valvular lesions, specially mitral and aortal. As associated congenital malformations, the patients prevailingly presented ventricular septal defect, mitral valve prolapse, arterial canal persistence, aortic stenosis, coarctation of the aorta. Blood cultures were collected and the most frequent identified etiological agents were: *Staphylococcus coagulase-positive, Streptococcus mitis, Staphylococcus speciae coagulase-negative, Staphylococcus haemolyticus, Streptococcus bovis, Escherichia coli***,** for which the antibiogram showed sensitivity for beta-lactam, cephalosporins, glycopeptides, trimethoprim-sulfamethoxazole, rifampicin, quinolone, lincosamides, oxazolidinones, and thus specific treatment was set up according to the antibiogram. **Conclusions**: The infectious endocarditis is a serious disease that affects young age too, leading towards exitus in some cases. Diagnostic imaging and early blood cultures are of relevance in order to intervene promptly. The treatment must be targeted and applied as fast as possible. **Keywords:** ENDOCARDITIS, HEMOCULTURES, CONGENITAL HEART MALFORMATIONS.

Infectious endocarditis is defined as the microbial infection of the endocardial surface (1). Infectious endocarditis represents "the infection of the endocardium with the presence of microorganisms at the level of the lesion" indicating that it may be the valvular, parietal endocardium, of some septal defects or a persistent arterial canal. This is a descriptive definition that stresses out the initial endocardial modifications, more frequent when addressed from a cardiologic perspective (2).

Over the last 50 years, major changes occurred in infectious endocarditis. There was a steep decrease in mortality, the etiological spectrum modified, new antibiotics and new lab techniques appeared, echocardiography developed and the susceptible population modified, the rate of the immune-compromised individuals and of the ones with prosthetic valves or pacemaker growing over those with rheumatic valvular disease (1).

Almost 10% of the endocarditis cases include pediatric population around the age of 10 (3, 4).

The incidence of the infectious endocarditis varies according to the location of the world population, thus 17 to 145 cases in a million persons being recorded per year. Despite new sophisticated cardiac procedures and early intervention, they still led to an increase of the endocarditis incidence in children with congenital heart defects. Pre-existent heart malformations are discovered in approximately 75-90% of children with infectious endocarditis (5). This increasing incidence noted in the last period is due to the growing survival rate in MCC, and to the more frequent use of central venous catheters, artificial valves and prosthetic material, as well as intravenous infections (including the drug users) (6).

At present, the mortality rate in pediatric patients with infectious endocarditis is of approximately 16-25% (5).

The etiological agents most frequently involved are: *Streptococcus viridans* (alpha-hemolytic) *Staphylococcus aureus*, *Streptococcus* species, *Enterococcus* species (more than 80% of EI), Gram-negative bacteria of HACEK group (responsible of 1-4% of EI), *Candida* and other fungi (< 10% of EI) (1).

Group B streptococcus and pneumococcus can also be met in the new-born. The gram-negative bacteria, the anaerobes and fungi appear especially in postoperative IE. IE is rare in nurslings, where it can appear only in association with open-heart interventions or with central venous catheters use (6).

The risk factors are represented mostly by the alteration of the structural integrity of the heart, respectively congenital heart malformations, especially the cyanotic ones, heart catheterization and procedures of vascular surgery, infections and interventions in the field of dentistry, ENT. The gastrointestinal and urogenital surgical interventions are not to be neglected, lately contested as being risk factors.

Specialized literature describes different localizations, the valve most frequently affected is the mitral (45-50% of cases) followed by the aortic (35-39%) and the tricuspid (19%). IE on pulmonary valve is less met (1.5-2%), or extravalvular, on the atrial septum, the ventricular wall, the cordage tendon (1).

The clinical diagnosis implies, in association, major criteria (positive blood cultures, highlighting the valvular damage at the echocardiographic examination) and minor criteria (fever, glomerulonephritis manifestations, Osler nodules, predisposing cardiac factors, suggestive echocardiographic images but not conclusive enough to be considered a major criteria, splenomegaly, increased VSH, increased CRP, the presence of the venous catheters, microscopic hematuria).

The bacteriologic diagnosis consists in highlighting the etiologic agent in blood cultures (3 samples are recommended), and the transthoracic and/or transesophageal echocardiography performed in dynamics allow certain affirmation of the valvular changes (7, 8, 9).

Taking into consideration that the infectious endocarditis remains a problem to consider at a young age, and the involved factors are more and more often met, this study aims to highlight issues commonly encountered, for a better knowledge of the disorder and a faster intervention.

MATERIAL AND METHODS

We have performed a retrospective study using epidemiological, clinical, off-clinical

and therapeutic data of 16 pediatric patients diagnosed with infectious endocarditis and hospitalized in the Cardiology Department, Clinic I of Pediatrics of the „Sf. Maria" Children Emergency Hospital of Iasi, during January 2007 – February 2011.

RESULTS AND DISCUSSION

During January 2007 – February 2011, in the Pediatric Cardiology Department of the „Sfânta Maria" Children Emergency Hospital of Iaşi, 16 children were diagnosed with infectious endocarditis (tab. I).

TABLE I

Epidemiological and social demographic data

Infectious endocarditis	2007	2008	2009	2010	2011	Total
No. of cases	2	3	5	4	2	16

The patients were aged 23 days to 16 years, most of the cases being recorded at the age group of 5 months – 8 years (9 cases), the average age being 4 years. The patients were coming mostly from urban locations (10 cases), the masculine gender being the most affected (10 cases). Regarding symptoms and clinical signs on admission in all 16 cases was observed occurrence of heart murmurs new fever was present in 81.25% of cases, and fatigue was noted in 93.75% of cases (tab. II).

TABLE II

Clinical aspects at hospitalization

Symptoms and clinical signs	Cases	%
Heart murmurs	16	100.00
Physical and mental fatigue	15	93.75
Fever, shiver	13	81.25
Little effort dyspnea	11	68.75
Chest pains	8	50.00
Cough	8	50.00
Headache	6	37.50
Loss of appetite	7	43.75
Dizziness, paralysis, paresthesia	5	31.25
Weight loss	5	31.25
Myalgia / arthralgia	3	18.75

At approximately 88% of the patients (14 cases), the endocardial damage appeared in the preexistent valvular lesions, especially mitral and aortic.

As associated congenital malformations, the patients predominantly presented ventricular septum defect, mitral valve prolapse, arterial canal persistence, aortic stenosis, coarctation of the aorta.

In all patients, the echocardiographic aspect represented a major criterion for the diagnosis of infectious endocarditis. As localization, six cases of IE on the pulmonary valve, two on the mitral valve, three localizations at the level of the aortic one, and three on the tricuspid valve. The imagistic description that came to our attention was of one of the patients (diagnosed previously with oper-

ated optical glioma) that presented several localizations (5 in number) that is on the aortic, pulmonary, mitral, tricuspid valve, and at the tip of the left ventricle (tab. III).

TABLE III
Echocardiographic distribution of the vegetations

Echocardiographic localizations of the vegetations	Cases	%
Mitral valve	6	37.50
Aortic valve	4	25.00
Tricuspid calve	3	18.75
Pulmonary valve	2	12.50
Normal	1	6.25

Five cases presented in association pulmonary hypertension.

Regarding the character of the vegetations, 81.25% had dimensions < 10 mm and only in 12.5% of cases the vegetations were > 10 mm (tab. IV).

TABLE IV
The character of the vegetations reported to the number of cases

The character of the vegetations	Cases	%
Mobile vegetations	14	87.50
Vegetations <10 mm	13	81.25
Big vegetations (>10 mm)	2	12.50
Multiple localizations of the vegetations	1	6.25

Aortic regurgitation was met in 6 cases (37.5%), the mitral regurgitation in 3 cases (18.75%), and the tricuspid one in 7 cases (43.75%).

The diagnosis associated was often present and affected patient's evolution: mitral insufficiency, aortic insufficiency, tricuspid insufficiency, aortic stenosis, severe pulmonary hypertension.

Blood cultures were collected and the most frequent identified etiological agents were: *Staphylococcus coagulase-positive, Streptococcus mitis, Staphylococcus speciae coagulase-negative, Staphylococcus haemolyticus, Streptococcus bovis, Escherichia coli***,** for which the antibiogram showed the sensitivity for betalactamine, cephalosporin, glycopeptide, trimethoprim-sulfamethoxazole, rifampicin, quinolone, lincosamides, oxazolidinone, and thus treatment according to the antibiogram was given.

Antibiotherapy with wide spectrum was mainly of first intention, monotherapy with aminopenicilin that is quinolone was administered in each case, cephalosporine of 3rd generation + quinolone in 4 cases, amonopenicilin + glycopeptides in 4 patients, carbapenemes + oxazolidinones in 2 patients, carbapenemes in 2 patients, glycopeptides + rifampicin 1 case, fluoro-quinolone + lincosamide 1 case, beta-lactamin + lincosamide 1 case.

The given treatment led to negativity of the blood cultures in the first 4 - 7 days, but it was necessary to extend the antibiotherapy for sterilization of the vegetations that were present echocardio-graphically.

The echocardiographic reevaluation as well as the cardiologic consultation in dynamics allowed an adequate and permanent monitoring of the therapeutic behavior.

The complications of cardiac type appeared despite the applied treatment and of the performed reevaluations (tab. V) .

TABLE V

Complications that appeared during the evolution of the pediatric patients

Complications	Cases
Heart failure	11
Pericarditis	6
Thromboembolism	4

Approximately 50% of the patients evolved favorably, in 5 cases (approx. 30% of the patients) it has been surgically intervened with an as complete as possible resection of the vegetations, restoring of valvular and ventricular function and correction of the risk factor (subjacent cardiopathy), and for 2 of the patients (approx. 15%) this problem was lethal.

CONCLUSIONS

Infectious endocarditis is a serious injury that reaches young age too, leading to death in some cases.

The different associated cardiac malformations - present more often in pediatric clinical reality- are an important predisposing factor for IE.

The imaging diagnosis and early blood cultures are of particular importance in order to intervene promptly.

The applied treatment must be fast and targeted.

The pediatric patients with surgery indication must be monitored after surgery, in order to rule out any complications.

TUBERCULOUS MENINGITIS – CLINICAL AND EPIDEMIOLOGICAL CONSIDERATIONS (A RETROSPECTIVE STUDY 2008 - 2011) (Abstract): Tuberculous meningitis represents one of the most severe forms of tuberculosis and is often a difficult diagnostic and therapeutic problem. The objective of this study is to analyze the cases of tuberculous meningitis in our region. **Material and Methods** We retrospectively analyzed 76 observation sheets of patients aged 4 months to 84 years, diagnosed with tuberculous meningitis, admitted to Infectious Diseases Hospital Iaşi during 2008 to 2011. **Results:** Tuberculous meningitis has affected mostly males (65.7%). Only a small proportion of patients (23.68%) had tuberculosis in their personal history. 26.2% were diagnosed also with other localization of tuberculosis (mostly pulmonary). Fever was identified in only 43.4% of cases; 40% of patients had an altered conscience at admission. The outcome was favorable in all cases. **Conclusions:** Tuberculous meningitis predominantly affects males, almost equally affects patients with other focuses of TB and those with a history of tuberculosis disease. **Key words**: QUANTIFERON, CEREBROSPINAL FLUID, MENINGITIS

Tuberculosis remains a frequent disease in our country (1, 2). Tuberculous meningitis represents one of the most severe forms of tuberculosis (3).

MATERIAL AND METHODS

We evaluated 76 cases of tuberculous meningitis admitted in the Hospital of Infectious Diseases Iaşi between 2008 and 2011, taking into account the clinical and biological aspects. We studied the incidence of new cases and the distribution of these cases according to age, gender, the way they were diagnosed and according to evolution under specific treatment.

We have taken into account the following aspects (as they result from the admission paper) - age, sex, a personal history of tuberculosis, a diagnosis of tuberculosis at other site than CNS, the presence of other diseases (cancer, diabetes, other conditions that can cause immunosupression), the clinical presentation, laboratory exams – the CSF direct exam, culture results, the Quantiferon test.

We also evaluated the treatment – time elapsed between admission and the initiation of specific therapy, the evolution of CSF parameters with treatment and the adverse effects.

RESULTS

Tuberculous meningitis afected mostly male patients (50 cases / 65.7%).

The distribution according to age groups was as follows- 9 patients (11.84%) with ages between 0 and 20 years, 18 patiens (23.68%) with ages between 21 and 30 years, 12 cases with ages between 31 and 40 years (15.78%), 7 cases with ages between 41 – 50 years (9.21%), 12 patients with ages between 51 and 60 years (15.78%), 6 cases (7.89%) with ages between 61 and 70 years and 12 cases (15.78%) with ages over 71 years.

We notice a higher incidence of tuberculous meningitis among teenagers and young adults.18 patients (23.68%) had a personal history of pulmonary tuberculosis (but not active pulmonary disease). 20 patients had simultaneous tuberculous with other localization (different from CNS), as follows – 16 patients (21.05%) with pulmonary tuberculosis, 3 patients (3.94%) with pleural tuberculosis, one patient with both pulmonary and pleural disease and one patient with tuberculous arthritis of the left knee.

Three patients had a personal history of neoplastic disorders (multiple myeloma, melanoma, Hodgkin's disease); 3 patients had a personal history of diabetes mellitus.

The time elapsed between the onset of symptoms that could be related to meningitis and admission varied, but for the majority of patients (53 - 69.73%), this period had an average duration of 14 days. The period of time between the suspicion of tuberculous meningitis and the moment when the specific therapy was initiated was usually one or two days.

Fever was present in 33 (43.42%) patients. In 35 (40.50%) cases, we identified an altered conscience. 59 (77.63%) had meningeal signs. The degree of neurological involvement was variable 40 (52.63%) were admitted with no neurological disturbances, 24 (31.57%) had minor neurological signs (cranial nerve involvement) and 12 (15.80%) had major neurological disturbances - seizures, major motor deficits (paresis or plegia).

The exam of the cerebrospinal fluid (CSF) has an important diagnostical value. In 6 (7.89%) patients, at the direct exam of the CSF was noticed the presence of *Mycobacterium tubeculosis* (using the Ziehl Neelsen stain). Furthermore, CSF cultures were positive in 37 patients (46.68%). The plasmatic Quantiferon test was positive in 16 patients (21.05%) (tab. I).

TABLE I
The number of CSF elements at admission

No. elements/mmc	No. cases	%
1 – 200	37	48.68
201 – 500	27	35.52
>500	12	15.78

At the time of the first control evaluation (by spinal tap) the number of elements in CSF varied as follows in Table II.

TABLE II
The dynamic of CSF elements

No.elements / mmc	No. cases	%
1 – 200	46	60.52
201 – 500	15	19.74
>500	15	19.74

Etiological treatment – all patients received the quadruple association of antituberculous drugs Isoniazide - 50 mg/kg b.w./day, Rimfapicin - 10 mg/kg b.w./day, Etambutol – 15 to 25 mg/kg b.w./day, Pirazinamid - 20 to 25 mg/kg b.w./day, for the duration of hospitalization (a average duration of 21 days), with the recommendation of continuing the treatment up to 1 year. The pathogenic treatment - with in-

travenous corticosteroid therapy (Dexamethasone) in all cases, with an average duration of 8 days.

DISCUSSION

The outcome is influenced by age (more severe in extreme age groups), the evolutional state of meningitis at admission, the neurological status of the patient, the progression of CNS involvement and the co morbidities (4).

Most of the patients in this study had ages between 20 and 60 years, which could explain the favorable evolution. Furthermore, most of the patients were admitted with no major neurological involvement.

In this study there were no deaths (although two patients were transferred in ICU wards). Because The Clinical Hospital of Infectious Diseases Iaşi receives patients from the entire North-East region of the country, the discharged patients do not always come back for check-up, so we cannot have a clear picture of their evolution.

Tuberculous meningitis is the most severe form of *M. tuberculosis* infection. It is also the most common form of CNS tuberculosis (3).

An early diagnosis and a rapid specific treatment can reduce mortality and associated morbidity (5, 6). The treatment is usually no less than 9 months. The pathogenic treatment with dexamethasone, although still controversial, is successful in reducing morbidity (7), especially in HIV-positive patients.

An increased mortality can be seen in patients with other major diseases, in those patients with severe neurological involvement at the time of the admission, in patient with a rapid evolution and in extreme age groups (8).

CONCLUSIONS

The incidence of tuberculous meningitis is influenced by the tuberculosis epidemics. In our study, the disease was most common at the young adult, affecting more frequently the male sex.

Only a small proportion of patients (23.68%) had tuberculosis in their personal history.

Although the tuberculous meningitis does not evolve as fast as other bacterial meningitis, the antituberculous therapy must be initiated at the first suspicion of *M. tuberculosis* infection. Any delay can influence the outcome. The suspicion of tuberculous meningitis appears in the presence of clinical signs (meningeal signs, gradual involvement), laboratory findings (the CSF exam, with a number of elements usually between a few hundreds and one thousand, with increased proteins and decreased glucose) end epidemiological data (a personal history of tuberculosis or contact with a known case of pulmonary tuberculosis).

A rapid diagnostic and an early treatment are essential in reducing the mortality and morbidity of this formidable disease.

NEWS

PLANTS USED IN AYURVEDIC AND TRADITIONAL CHINESE MEDICINE MODULATE AMYLOID PRECURSOR PROTEIN

Alzheimer's disease, the most common form of dementia, is characterized by memory and cognitive impairment, speech loss and personality changes. The main pathological event is the accumulation of neuritic plaques composed of β-amyloid peptide (Aβ). This peptide is generated through the proteolysis of a transmembrane glycoprotein named amyloid-β-precursor protein (APP). The non-amyloidogenic cleavage of APP leads to α soluble APP (sAPPα), p3 peptide and APP intracellular domain (AICD) while the amyloidogenic cleavage generates soluble APPβ (sAPPβ), Aβ and AICD. As it is estimated that 115.4 million people will suffer from this disease by 2050, numerous efforts are done to discover new therapeutic agents that reduce Aβ accumulation. This study reports on *in vitro* screening on APP modulation of 15 herbs used in Ayurvedic and Traditional Chinese medicine for the treatment of cognitive disorders. N2a-SweAPP cells (mouse neuroblastoma N2a cells that have been stably transfected with human Swedish mutant APP) were treated with different doses of ethanolic extracts of tested herbs; the Aβ levels in the supernatant were determined by ELISA. The extracts showing a significant inhibition on Aβ production, namely extracts of *Polygonum multiflorum* Thunb. roots and *Convolvulus pluricaulis* Choisy. leaves, were further subjected to an APP modulation assay. In this respect, their effects on sAPPα and sAPPβ were studied through western blot analysis. Only the extract of *Polygonum multiflorum* Thunb. roots showed APP modulation activity by up-regulating sAPPα and down-regulating sAPPβ. This result justifies not only the traditional uses of the plant but also further investigations on the therapeutic potential of this species. (Liu L-F, Durairajan SSK, Lu J-H, Koo I, Li M. In vitro screening on amyloid precursor protein modulation of plants used in Ayurvedic and Traditional Chinese medicine for memory improvement. *J Ethnopharmacol* 2012; 141: 754-760).
